htf - Hardware Testing Framework

htf is a professional **Hardware Testing Framework** based on Python to easily realize **Automated Hardware Tests**. It has a strong focus on reporting, industrial applications and functional safety and integrates seamlessly with Continuous Integration and Continuous Delivery as well as end-of-line testing systems.

What makes htf special?

- It allows you to **build teststands** using Python-based tests for **realtime testing** with diverse hardware (PLC, Development-Boards, PyVisa, Arduino etc.).
- It supports Behaviour Driven Development (BDD) to write low-code tests without prior coding experience.
- It enables you to implement powerful tests in plain Python, too.
- It provides you with the possibility to run interactive testing in case full automation is not possible and manual tests are required.
- It produces visual Test Reports which can be showed to your clients or stakeholders.
- It integrates seamlessly with QABench, which means it works smoothly with our Dashboard, allowing for **easy management and tracking** of requirements coverage.
- It can be used **for free** with the community edition.

The framework can be easily extended to your liking, either by yourself or with our support. If you need help or have questions of any kind, send us an e-mail.

If you prefer video showcases, take a look at our demo.

Test Examples

Behavior Driven Development:

```
Feature: Device Boot
  Requirements: REQ-Boot-1
  Tags: boot

  Scenario: Boot Device
    Given the device is shut down
    And the power supply is set to 0 V
    When the power supply is switched 24 V
    And the power button is set to on
    Then the device boots up
    And the device is be running after 10 seconds
```

Python:

```
@requirements("REQ-Boot-1")
@tag("boot")
async def test_boot(device, power_supply, delay):
   """
   This tests checks that the device can be booted.
   """
   with step("Shut down device"):
      await device.shut_down()
      await power_supply.power_off()

   with step("Switch on device"):
      await power_supply.power_on()
      await device.switch_on()

   with step("Check that the device boots up within 10 s"):
      delay(10)
      assert_true(device.is_up_and_running(), "The device did not boot up within 10 s")
```

Getting Started

To get started, take a look at the installation instructions, the introduction and how to write tests, fixtures and available test reports.

Learn how to run tests from the command line and Python scripts.

If you prefer a more guided introduction take a look at our HILSTER Testing Framework Demonstrator.

Example

```
import htf

def test_example(step, assertions, attachments, threads):
   with step("Tests can be structured with steps"):
      assertions.assert_true(True, "This step succeeds")

      with step("Attach a file if the outer step succeeds"):
         attachments.attach_file("graph.png", "Important graph")

   with step("Run something in the background"):
      def tick():
         while True:
            print('tick')
      threads.run_background(tick)

if __name__ == "__main__":
   htf.main()
```

Contact

The framework can be easily extended to your liking, either by yourself or with our support.

If you have any questions or ideas, please don't hesitate and e-mail us via `support@hilster.io`.

Documentation

Introduction

Welcome to the HILSTER Testing Framework documentation. HILSTER Testing Framework (htf) is a part of QABench.

HILSTER Testing Framework is a professional Python Testing Framework with a strong focus on reporting, industrial applications and functional safety. We are committed to enabling well structured and easy to understand tests. You can find a demo of the main features of HILSTER Testing Framework at htf-demo.

The HILSTER Testing Framework is developed and maintained by HILSTER. HILSTER offers continuous updates as well as customer support.

htf is free to use with a community license. Commercial licensing options are available.

Applications include: hardware-in-the-loop, hardware-software integration tests, system tests, end-of-line tests, as well as unittests and software-software integration tests.

Key features are: state-of-the-art test runner with fixtures and minimal overhead, tagging, smart reporting, interactive testing, data driven testing and behavior driven development.

htf seamlessly integrates with your existing continuous integration setup.

Working with binary data structures and communication protocols is comfortable using OSER.

For questions and suggestions, please contact us.

Have a lot of fun!

Editions

htf is offered as part of a community edition and a commercial edition.

The community edition allows private persons to use htf for free and allows up to 3 users in a commercial context.

If you need more than three users, please get a commercial edition.

Edition Comparison

	Community Edition	Commercial Edition
Use for free in private context	Yes	No
Use for free in commercial context	Yes, but only for up to 3 users	No
Number of users	Up to 3 users	Depends on the edition

Community Edition

The community edition contains a edition file for the core features of htf.

In order to use the community edition, please read about Installing the community version. Please also note our End-User License Agreement (EULA) and our Privacy Policy.

Note

End-User License Agreement (EULA) of HILSTER Testing Framework (htf)

This End-User License Agreement (“EULA”) is a legal agreement between you and HILSTER

This EULA agreement governs your acquisition and use of our HILSTER Testing Framework (htf) software (“Software”) directly from HILSTER or indirectly through a HILSTER authorized reseller or distributor (a “Reseller”).

Please read this EULA agreement carefully before completing the installation process and using the HILSTER Testing Framework (htf) software. It provides a license to use the HILSTER Testing Framework (htf) software and contains warranty information and liability disclaimers.

If you register for a free trial of the HILSTER Testing Framework (htf) software, this EULA agreement will also govern that trial. By clicking “accept” or installing and/or using the HILSTER Testing Framework (htf) software, you are confirming your acceptance of the Software and agreeing to become bound by the terms of this EULA agreement.

If you are entering into this EULA agreement on behalf of a company or other legal entity, you represent that you have the authority to bind such entity and its affiliates to these terms and conditions. If you do not have such authority or if you do not agree with the terms and conditions of this EULA agreement, do not install or use the Software, and you must not accept this EULA agreement.

This EULA agreement shall apply only to the Software supplied by HILSTER herewith regardless of whether other software is referred to or described herein. The terms also apply to any HILSTER updates, supplements, Internet-based services, and support services for the Software, unless other terms accompany those items on delivery. If so, those terms apply. This EULA was created by EULA Template for HILSTER Testing Framework (htf).

License Grant

HILSTER hereby grants you a personal, non-transferable, non-exclusive licence to use the HILSTER Testing Framework (htf) software on your devices in accordance with the terms of this EULA agreement.

You are permitted to load the HILSTER Testing Framework (htf) software (for example a PC, laptop, mobile or tablet) under your control. You are responsible for ensuring your device meets the minimum requirements of the HILSTER Testing Framework (htf) software.

You are **NOT PERMITTED** to:

- Edit, alter, modify, adapt, translate or otherwise change the whole or any part of the Software nor permit the whole or any part of the Software to be combined with or become incorporated in any other software, nor decompile, disassemble or reverse engineer the Software or attempt to do any such things
- Reproduce, copy, distribute or resell the Software
- Modify, adapt, or create derivative works of the Software without prior written consent from HILSTER

- Resell, sublicense, or redistribute the Software in any form, regardless of user or machine count
- Use the Software for any commercial purpose for more than 3 users
- Use the Software for any commercial purpose on more than 3 machines
- Allow any third party to use the Software on behalf of or for the benefit of any third party
- Use the Software in any way which breaches any applicable local, national or international law
- Use the Software for any purpose that HILSTER considers is a breach of this EULA agreement

Intellectual Property and Ownership

HILSTER shall at all times retain ownership of the Software as originally downloaded by you and all subsequent downloads of the Software by you. The Software (and the copyright, and other intellectual property rights of whatever nature in the Software, including any modifications made thereto) are and shall remain the property of HILSTER.

HILSTER reserves the right to grant licences to use the Software to third parties.

Termination

This EULA agreement is effective from the date you first use the Software and shall continue until terminated. You may terminate it at any time upon written notice to HILSTER.

It will also terminate immediately if you fail to comply with any term of this EULA agreement. Upon such termination, the licenses granted by this EULA agreement will immediately terminate and you agree to stop all access and use of the Software. The provisions that by their nature continue and survive will survive any termination of this EULA agreement.

Governing Law

This EULA agreement, and any dispute arising out of or in connection with this EULA agreement, shall be governed by and construed in accordance with the laws of de.

Note

Privacy Policy

At HILSTER License Server, accessible from https://licenses.hilster.io, one of our main priorities is the privacy of our visitors. This Privacy Policy document contains types of information that is collected and recorded by HILSTER License Server and how we use it.

If you have additional questions or require more information about our Privacy Policy, do not hesitate to contact us.

General Data Protection Regulation (GDPR)

We are a Data Controller of your information.

HILSTER legal basis for collecting and using the personal information described in this Privacy Policy depends on the Personal Information we collect and the specific context in which we collect the information:

HILSTER needs to perform a contract with you You have given HILSTER permission to do so Processing your personal information is in HILSTER legitimate interests HILSTER needs to comply with the law HILSTER will retain your personal information only for as long as is necessary for the purposes set out in this Privacy Policy. We will retain and use your information to the extent necessary to comply with our legal obligations, resolve disputes, and enforce our policies. Our Privacy Policy was generated with the help of GDPR Privacy Policy Generator and the GDPR Privacy Policy Generator.

If you are a resident of the European Economic Area (EEA), you have certain data protection rights. If you wish to be informed what Personal Information we hold about you and if you want it to be removed from our systems, please contact us.

In certain circumstances, you have the following data protection rights:

- The right to access, update or to delete the information we have on you.
- The right of rectification.
- The right to object.
- The right of restriction.
- The right to data portability
- The right to withdraw consent

Log Files

HILSTER License Server follows a standard procedure of using log files. These files log visitors when they visit websites. All hosting companies do this and a part of hosting services' analytics. The information collected by log files include internet protocol (IP) addresses, browser type, Internet Service Provider (ISP), date and time stamp, referring/exit pages, and possibly the number of clicks. These are not linked to any information that is personally identifiable. The purpose of the information is for analyzing trends, administering the site, tracking users' movement on the website, and gathering demographic information.

> **Consent**
>
> By using the community edition, you hereby consent to our Privacy Policy and agree to its terms.

Commercial Edition

To get a commercial edition, please contact us via e-mail.

ALM/QMS Integrations

HILSTER Testing Framework seamlessly integrates into many Application Lifecycle Management Systems and Quality Management Systems.

Matrix Requirements

Matrix Requirements is an Application Lifecycle Management System and Quality Management System made to design medical products.

QABench offers an integration (called `htf-matrixreq`) to enable specification of tests within Matrix Requirements, as well as sending test results back.

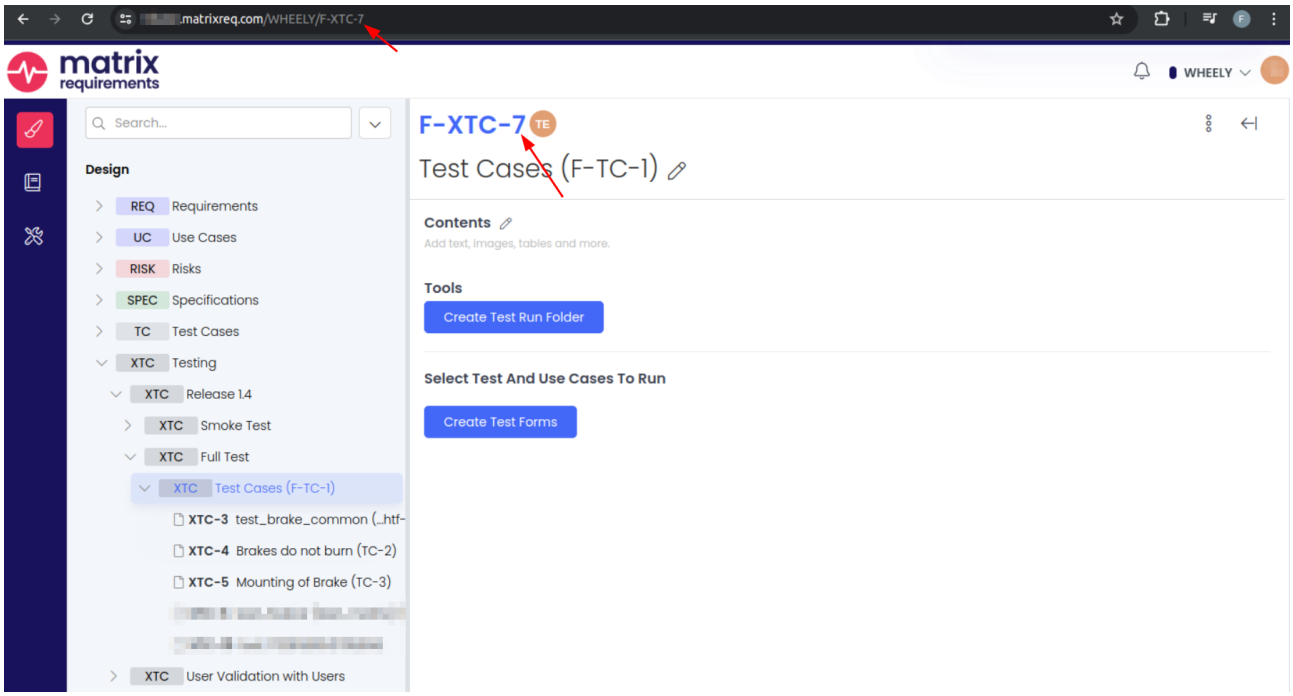
Installation

`htf-matrixreq` is included when `htf[full]` is installed on your system. It can also be installed explicitly with `htf[matrixreq]`.

See installation instructions for more details.

General Usage

In general, Matrix Requirements allows you to create and manage requirements. In addition, it allows you to specify tests that cover these requirements, and therefore link to them.



For tests, multiple test executions can be created and managed in folders.

`htf-matrixreq` is run with at least one of these folder ids, recursively collects the test execution items, finds the corresponding test specifications, runs the test and sends back the results for the implemented tests to the corresponding test execution items automatically.

`htf-matrixreq` needs at least one test execution folder in Matrix Requirements. To create that please follow the instructions in the Matrix Requirements Documentation.

Tests that will be run need to implement at least on test specification. See Linking Implemented Tests for more details.

To get the id of the test execution folder, simply click on it in the browser and get the id from the url or the title.

In the example, the test execution folder id is `F-XTC-7`.

Linking Implemented Tests

You can link the implemented Matrix Requirements test specifications in to tests in `htf` using the decorator :func:`htf.implements` for script based tests or using the `Implements:` keyword for BDD tests.

The following example shows a test with linked test specifications in Python.

```
@htf.implements("TC-1", "https://<user>.matrixreq.com/<project>/TC-2")
def test_testcase_1_and_2(step):
    with step("First test step", expected_result="This step succeeds"):
        assert True

    with step("Second test step", expected_result="This step succeeds, too"):
        assert True
```

The following example shows a corresponding test in BDD.

```
Feature: Feature with implemented tests

    Implements: TC-1, https://<user>.matrixreq.com/<project>/TC-2

    Scenario: Scenario with implemented tests
        Implements: TC-3
        # ...
```

API Token

`htf-matrixreq` uses the Rest API of Matrix Requirements and thus needs an API token to function. To create an API token, login into Matrix Requirements and navigate to `https://<user>.matrixreq.com/adminConfig/Token`.

Create an API token and store it.

Usage from Command Line

`htf-matrixreq` supports the same command line arguments as `htf` does and adds a few other.

For example to run all tests in the folder `tests` for the test execution folder ids `F-XTC-1` and `F-XTC-7`, run:

```
htf-matrixreq --items F-XTC-1,F-XTC-7 tests/
```

A full example in which all options are set via command line would be:

```
htf-matrixreq \
    --host https://<user>.matrixreq.com \
    --project <project> --items F-XTC-1,F-XTC-7 \
    --token <token> \
    --set Tester=tester \
    --set Version=1.2.3 \
    tests/
```

This example also sets the extra fields `Version` and *Tester* ` within the Matrix Requirements test execution item, and gets all other options from command line.

Usage in Python

`htf.matrixreq.main` supports the same parameters as `htf.main` does and adds a few other.

```
from htf.matrixreq import main

if __name__ == "__main__":
    main(
        host="https://<user>.matrixreq.com",
        project="<project>",
        token="<token>",
        items=["F-XTC-1", "XTC-7"],
        extra_fields={
            "Tester": "tester",
            "Version": "1.2.3",
        },
        tests=["tests/"],
    )
```

`htf.matrixreq.run` is an alias for `htf.matrixreq.main`.

Python Functions

```
htf.matrixreq.main(host: str | None = None, project: str | None = None, items: List[str] |
None = None, token: str | None = None, extra_fields: Dict[str, str] | None = None, insecure:
bool = False, date_format: str = 'yyyy/MM/dd', date_time_format: str = 'yyyy/MM/dd HH:mm:ss',
*htf_args: Any, **htf_kwargs: Any) → int
```

The htf.matrix.main() and `htf-matrixreq` command line utility is used to run tests and send the results back to Matrix ALM/QMS.

Parameters:

- **project** – the name of the project
- **items** – the items to search for test execution item
- **token** – the REST API token
- **extra_fields** – extra fields to set for updated test execution items
- **insecure** – if set to `True` SSL/TLS certificates are not checked
- **(default** (*date_time_format*) – “yyyy/MM/dd”): the date format for the project
- **(default** – “yyyy/MM/dd HH:mm:ss”): the date time format for the project
- ***htf_args** – htf positional arguments
- ****htf_kwargs** – htf keyword arguments

Returns:
the return code of `htf.main()` plus the number of errors and warnings produced by this tool.
Return type:
int

```
htf.matrixreq.run(host: str | None = None, project: str | None = None, items: List[str] |
None = None, token: str | None = None, extra_fields: Dict[str, str] | None = None, insecure:
bool = False, date_format: str = 'yyyy/MM/dd', date_time_format: str = 'yyyy/MM/dd HH:mm:ss',
*htf_args: Any, **htf_kwargs: Any) → int
```

The htf.matrix.main() and `htf-matrixreq` command line utility is used to run tests and send the results back to Matrix ALM/QMS.

Parameters:

- **project** – the name of the project
- **items** – the items to search for test execution item
- **token** – the REST API token
- **extra_fields** – extra fields to set for updated test execution items
- **insecure** – if set to `True` SSL/TLS certificates are not checked
- **(default** (*date_time_format*) – "yyyy/MM/dd"): the date format for the project
- **(default** – "yyyy/MM/dd HH:mm:ss"): the date time format for the project
- ***htf_args** – htf positional arguments
- ****htf_kwargs** – htf keyword arguments

Returns:
the return code of `htf.main()` plus the number of errors and warnings produced by this tool.
Return type:
int

Options

To use `htf-matrixreq`, you need to specify the hostname, the project name, the API token and, if needed, the insecure flag.

These options can either be set via command line options, by storing them in `htf.settings`, and by setting them via environment variables.

Environment variables are overwritten by `htf.settings`, whereas command line options overwrite everything else.

Command Line Options

To specify the hostname via command line, use `--host <host>`.

To specify the project name via command line, use `--project <project>`.

To specify the API token via command line, use `--token <API Token>`.

The full list of command line options is:

```
usage: htf-matrixreq [-h] [--host HOST] [--project PROJECT] --items ITEMS [--token TOKEN] [--
insecure]
                     [--set field1=value1,field2=value2,...,fieldN=valueN] [--date-format
DATE_FORMAT]
```

```
                    [--date-time-format DATE_TIME_FORMAT]

htf-matrixreq - HILSTER Testing Framework integration for Matrix Requiements ALM/QMS System
(HILSTER, https://hilster.io)

options:
  -h, --help            show this help message and exit
  --host HOST           The host of the Matrix Requirements project (required)
  --project PROJECT     The name of the Matrix Requirements project (required)
  --items ITEMS         The items to recursively search for tests in. Can be a comma-separated list
of items, e.g.
                        --item 'F-XTC-1,F-XTC-2'. (required, can be repeated)
  --token TOKEN         The REST API token to use (required)
  --insecure            Disable SSL/TLS certificate check (can be useful behind some proxy servers)
  --set field1=value1,field2=value2,...,fieldN=valueN
                        Set extra fields on every item, e.g. Tester, Version, etc. Can be repeated.
  --date-format DATE_FORMAT
                        The date format for the project.
  --date-time-format DATE_TIME_FORMAT
                        The date time format for the project.
```

Settings

You can specify hostname, project name, API token and the insecure flag in `htf.settings`, too.

To do that add a section in the settings called `matrixreq`.

YAML Example:

```yaml
matrixreq:
    host: https://<user>.matrixreq.com
    project: <project>
    token: <token>
    date_format: "yyyy/MM/dd"
    date_time_format: "yyyy/MM/dd HH:mm:ss"
    extra_fields:
        Tester: <tester>
        Version: <version>
    insecure: false  # true|false
```

JSON Example:

```json
"matrixreq": {
    "host": "https://<user>.matrixreq.com",
    "project": "<project>",
    "token": "<token>",
    "date_format": "yyyy/MM/dd",
    "date_time_format": "yyyy/MM/dd HH:mm:ss",
    "extra_fields" {
        "Tester": "<tester>",
        "Version": "<version>"
    },
```

```
    "insecure": false
}
```

You can leave out any value if it is not needed, or if it is specified elsewhere.

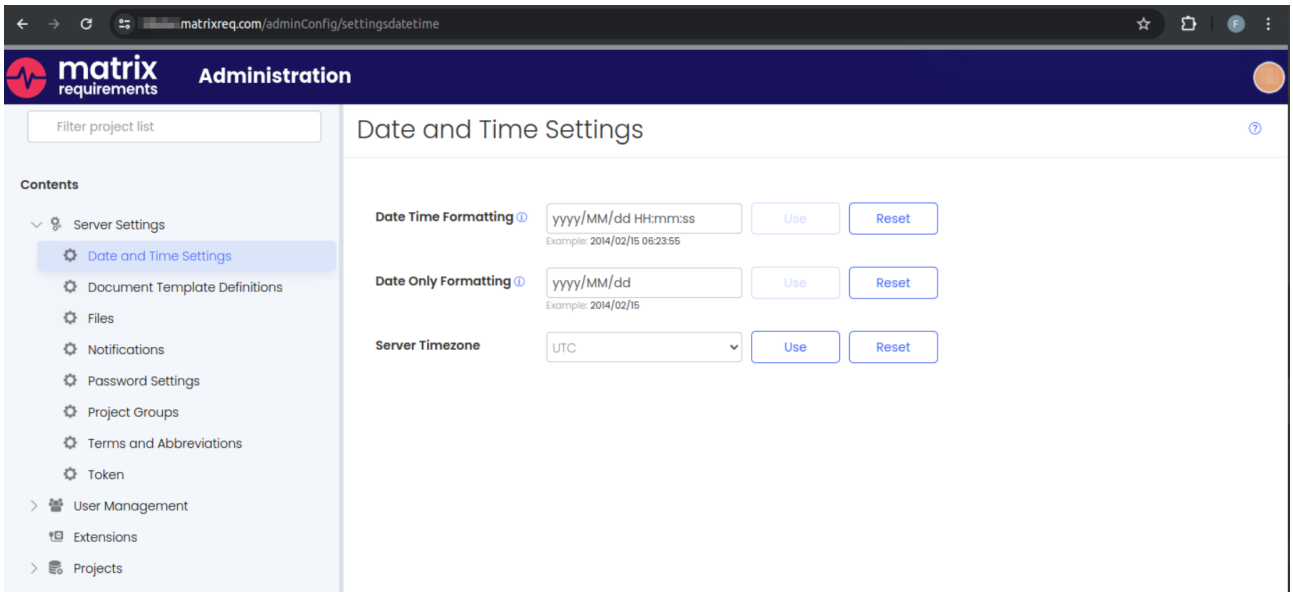
Environment Variables

The following tables shows the supported environment variables and their meaning.

Environment Variable	Meaning
MATRIXREQ_HOST	Hostname, e.g. https://<user>.matrixreq.com
MATRIXREQ_INSECURE	Disable SSL/TLS certificate verification. Any value is supported.
MATRIXREQ_PROJECT	Project Name
MATRIXREQ_TOKEN	API Token, e.g. <token>
MATRIXREQ_DATE_FORMAT	The date format. Default: “yyyy/MM/dd”
MATRIXREQ_DATE_TIME_FORMAT	The date time format. Default: “yyyy/MM/dd HH:mm:ss”

Setting Extra Fields

You can set extra fields within Matrix Requirements test execution items such as `Tester` or `Version` when sending test results back to test execution items.



To do this in the command line, add `--set name=value` pairs. For example in order to set the `Version` to `1.2.3`, use `--item Version=1.2.3`.

You can also set these extra values using `htf.settings`.

Date and Time Formats

`htf-matrixreq` needs to set the test execution timestamps in the specified format set within the Matrix Requirements project.

To view and change the formats, login into Matrix Requirements and navigate to `https://<user>.matrixreq.com/adminConfig/settingsdatetime`.

If the formats differ the test execution timestamps will not be set.

Proxy

You can specify proxies to use by setting the environment variable `https_proxy` to `https://<username>:<password>@<host>:<port>`.

On Linux enter:

```
export https_proxy=https://<username>:<password>@<host>:<port>
```

and on Windows enter:

```
set https_proxy=https://<username>:<password>@<host>:<port>
```

SSL/TLS Verification

In some circumstances it might be necessary to disable SSL/TLS verification. To do this simply add the option `--insecure` to `htf-matrixreq` or set the environment variable `MATRIXREQ_INSECURE` to any value.

On Linux enter:

```
export MATRIXREQ_INSECURE=true
```

and on Windows enter:

```
set MATRIXREQ_INSECURE=true
```

Debugging

To enable debugging of HTTPS communication set the environment variable `MATRIXREQ_DEBUG` to any value and `htf-matrixreq`.

On Linux enter:

```
export MATRIXREQ_DEBUG=true
```

and on Windows enter:

```
set MATRIXREQ_DEBUG=true
```

Changelog

htf-matrixreq-1.1.0

- ship `cp312-abi3` wheels that are compatible with Python 3.12 and newer versions

htf-matrixreq-1.0.3

- implement Cyber Resilience Act Conformity (CRA)
- update dependencies

htf-matrixreq-1.0.2

- add support for Python 3.13

htf-matrixreq-1.0.1

- fix setting of actual results

htf-matrixreq-1.0.0

- initial integration

IBM® Engineering Requirements Management DOORS

HILSTER Testing Framework offers an integration to enable specification of tests and requirements in IBM® Engineering Requirements Management DOORS as well as sending test results back.

See IBM® Engineering Requirements Management DOORS Test Report for more details.

Installation, Activation and Upgrading

Requirements

To install `htf`, Python 3.12 or newer is required.

`htf` is tested on Microsoft Windows and all Linux versions that support manylinux wheels. It also runs on `Raspberry Pi` computers.

Wheels for Python 3 on Linux are shipped using recent `manylinux` and `abi3` formats for `Python 3.12` and newer for 64-bit machines only.

We host our own pypi server.

For further information regarding the support of your specific project requirements, please contact our Support.

Installation on Windows

If Python is not already installed, please download and install Python using the official CPython installers or use a CPython distribution of your choice, e.g. WinPython.

It is recommended to install Python in the typical paths, e.g. `C:\Python312\` for Python 3.12 respectively.

If you want to install `htf` via `pip`, you need to add the `Scripts` folder of the Python distribution to your `%PATH%` environment variable (there is an option in the installer). `pip` is shipped with recent Python Windows distributions.

Installation on Linux

On most Linux distributions, at least one version of Python should be installed by default. Since 2020, this version should be Python 3.

`pip` can be installed by installing the packages `python3-pip` for Python 3.12, respectively. There are no other dependencies that need to be installed on Linux.

On Ubuntu for example, all dependencies should be satisfied using:

```
sudo apt install python3-pip
```

Installation on Raspberry Pi OS

You can easily install HILSTER Testing Framework on a Raspberry Pi OS using the 64 bit installation image available at downloads page.

Virtual environments with Virtualenvwrapper

It is generally recommended to separate project dependencies into different virtual environments.

More information about setting up and using virtual environments on Linux can be found in the python-guide and for Windows in the virtualenv docs.

It is recommended to use the `virtualenvwrapper` package, which provides functions that allow for a convenient handling of virtual environments. Further information can be found in the virtualenwrapper docs.

There is also a Windows port called virtualenvwrapper-win.

Virtual environments with uv

uv supports virtual environments, too.

To create a virtual environment, run:

```
uv venv <virtual-environment-name>
```

To activate the virtual environment, follow the activation instructions.

Installation using Anaconda

Alternatively Anaconda can be used as a multi-platform Python-Platform. Installers for Windows and Linux are provided by Anaconda. It is pre-packaged with multiple libraries especially from the data science community. Before moving on please download and install Anaconda on your system.

After the base install it is again recommended to separate project dependencies into different virtual environments. You can create a `conda` environment using the Anaconda Prompt:

```
conda create --name environment_name python
conda activate environment_name
```

Further references to the Anaconda Prompt can be found in the Anaconda docs.

You can then proceed to install `htf` via `pip`.

Installation of htf via pip

Given that Python is properly set up and the virtual environment of your choice is activated, you can simply install `htf` using pip:

```
pip install --index-url https://hilster.io 'htf[full]'
```

To install the community version, run:

```
pip install --index-url https://hilster.io htf-community
```

Herein, `--index-url https://hilster.io` adds the HILSTER Python package repository to the search index of pip so that the HILSTER packages can be discovered.

Depending on your installation, you might have to replace `pip` with `pip3`.

Installation of htf via uv

`htf` can also be installed using uv.

To install `htf`, run:

```
uv pip install --index-url https://hilster.io 'htf[full]'
```

To install the community version, run:

```
uv pip install --index-url https://hilster.io htf-community
```

Herein, `--index-url https://hilster.io` adds the `HILSTER Python package repository` to the search index so that the HILSTER packages can be discovered.

Installation options

`htf` comes with submodules that can be installed manually or using installation options.

Installation options are put behind the package in the `pip` prompt.

For example

```
pip install -i https://pypi.hilster.io htf
```

only installs the core of `htf`.

```
pip install -i https://pypi.hilster.io htf[full]
```

installs all possible options.

There is an installation option for all submodules, e.g. the option for `htf-modbus` is `[modbus]` and for `htf-hart` you can use `[hart]`.

Installation options can be combined as a coma-separated list:

```
pip install -i https://pypi.hilster.io htf[modbus,hart]
```

installs `htf-modbus` and `htf-hart`.

Another option is `htf[oser]` to install `oser` directly.

Installation behind a corporate proxy

If you are behind a corporate proxy, there are several ways to tell `pip` about the proxy url and your credentials.

The simplest solution is to just use the `--proxy` argument

```
pip install -i https://pypi.hilster.io --proxy=http://<username>:<password>@<host>:<port> htf
```

If you want to persist the `proxy` settings, it is recommended to store them in the pip configuration file `pip.ini`, which is stored in the `pip` folder in your home directory.

```
[global]
proxy = http://<username>:<password>@<host>:<port>
```

Another solution is use the environment variable `https_proxy`.

On Linux enter:

```
export https_proxy=https://<username>:<password>@<host>:<port>
```

and on Windows enter:

```
set https_proxy=https://<username>:<password>@<host>:<port>
```

and continue with the installation without the `--proxy` option.

Activation

HILSTER's license server is used for remote activation.

Activation is not needed if you use the community edition, since a license is already included.

To activate non-community versions of the software, you need one or more activation keys that HILSTER sent you.

An activation key consists of `16` upper case letters in `4` groups concatenated by dashes.

```
hlm activate ABCD-EFGH-IJKL-MNOP
```

You can also activate more then one activation key at a time.

```
hlm activate ABCD-EFGH-IJKL-MNOP QRST-UVWX-YZAB-CDEF  # ...
```

Activation creates a license that is stored locally.

To renew the licenses once activated, simply run

```
hlm renew
```

When you are behind a proxy, you have to set the environment variable `https_proxy` like in the installation process.

Every virtual environment has to be activated separately.

Check installation

To list your licenses, run

```
hlm list
```

If htf prints a version, it is unlockable

```
htf version  # prints the version
```

Upgrading

To upgrade add the `-U` option:

```
pip install -i https://pypi.hilster.io -U htf
```

If you are using a proxy you must add the `--proxy` option or set environment variables like described above.

Installing a specific version

To install a specific version use

```
pip install -i https://pypi.hilster.io htf==2.0.0
```

for example.

If you are using a proxy you must add the `--proxy` option or set environment variables like described above.

Automatic check for updates

`htf` checks for available updates at the end of a test run automatically. This can be disabled by setting the `HTF_DISABLE_UPDATE_CHECK` environment variable.

On Linux enter:

```
export HTF_DISABLE_UPDATE_CHECK=1
```

and on Windows enter:

```
set HTF_DISABLE_UPDATE_CHECK=1
```

Installing the community version

To install the community version, run

```
pip install -i https://pypi.hilster.io htf-community
```

Manual activation is not needed because the community license is already included and the activation will be performed automatically.

Make sure to use a recent Python version to install the latest version for `htf-community`. Read installation requirements for more information.

The available wheels and supported Python versions can also be found on HILSTER's PyPI server, too.

Support

Don't panic — we can help you!

Send us an e-mail.

Alternatively, contact our support team by running

```
support
```

from the command line and following the instructions.

Writing Tests

htf includes a state of the art test runner that supports three different types of tests: functions, coroutines and methods in simple classes or subclasses of `htf.TestCase`.

Each function or method or coroutine that starts with `test` or that is decorated with `htf.test` is assumed to be a test and is collected.

We recommend to use functions, coroutines or simple classes to build tests.

All tests can use Fixtures to set up their test environment.

Tests use Assertions to assert conditions of your tests.

Test Functions

The simplest way to create a test is to define a function. The function is assumed to be a test if the name starts with `test`, or the function is decorated with `htf.test`.

Example:

```
def test_function():
    pass

async def test_async_function():
    pass

@htf.test
def function():
    pass

@htf.test
def async_function():
    pass

if __name__ == "__main__":
    htf.main()
```

Test Classes

A class is a container for multiple test methods. The method is assumed to be a test if the name starts with `test`, or the method is decorated with `htf.test`.

Example:

```
class Tests:
    def test_method(self):
        pass

    async def test_async_method(self):
        pass

    @htf.test
    def method(self):
        pass

    @htf.test
    async def async_method(self):
        pass
```

Legacy Tests: TestCase

Unittest-like tests are also supported by subclassing `htf.TestCase`.

```
class LegacyTests(htf.TestCase):
    def test_method(self):
        pass

    async def test_async_method(self):
        pass

    @htf.test
    def method(self):
        pass

    @htf.test
    async def async_method(self):
        pass
```

`htf.TestCase.setUp`, `htf.TestCase.tearDown`, `htf.TestCase.setUpClass` and `htf.TestCase.tearDownClass` are also supported. These tests cannot be run with unittest as a test runner.

```
class htf.TestCase(method_name: str = 'run_test')
```

`TestCase` is the basic test case class for the HILSTER Testing Framework that should be used with inheritance.

Parameters:
method_name='run_test' – the name of the test method to be run by the test runner.

```
static assert_almost_equal(a: float, b: float, places: int | None = None, delta: float |
None = None, message: str | None = None) → None
```

Assert that `a` and `b` are almost equal. Useful to compare floating point numbers. Comparison is realized either using a maximum `delta` or the number of decimal `places`

Parameters:

- **a** – number
- **b** – number
- **places=None** – the number of decimal places for comparison. If `None` `7` decimal places are used.
- **delta=None** – the maximum delta
- **message=None** – the message to prepend to the error message

Raises:
AssertionError – if `a` and `b` are not almost equal.

```
static assert_dict_equal(a: Dict, b: Dict, message: str | None = None) → None
```

Assert that `a` equals `b` and that both are of type `dict`.

Parameters:

- **a** – a dict
- **b** – a dict
- **message=None** – the message to prepend to the error message

Raises:
AssertionError – if `a` and `b` are not equal.

```
static assert_equal(a: Any, b: Any, message: str | None = None) → None
```

Assert that `a` equals `b`. Tries to find a registered equality asserter and uses the base assert if no special assert is registered.

Parameters:

- **a** – an object
- **b** – an object
- **message=None** – the message to prepend to the error message

Raises:
AssertionError – if `a` and `b` are not equal.

```
static assert_false(expression: bool, message: str | None = None) → None
```

Assert that `expression` is `False`.

Parameters:

- **expression** – the boolean expression to be validated
- **message=None** – the message to prepend to the error message

Raises:
AssertionError – if `expression` is not `False`

```
static assert_greater(a: Any, b: Any, message: str | None = None) → None
```

Assert that `a` is greater than `b`.

Parameters:

- **a** – a comparable object
- **b** – a comparable object
- **message=None** – the message to prepend to the error message

Raises:
AssertionError – if `a` is not greater than `b`

```
static assert_greater_equal(a: Any, b: Any, message: str | None = None) → None
```

Assert that `a` is greater or equal to `b`.

Parameters:

- **a** – a comparable object
- **b** – a comparable object
- **message=None** – the message to prepend to the error message

Raises:
AssertionError – if `a` is not greater or equal to `b`

```
static assert_in(member: Any, container: Iterable, message: str | None = None) → None
```

Assert that `container` contains `member`.

Parameters:

- **member** – the object that shall be included in `container`
- **container** – an iterable to search for `member`
- **message=None** – the message to prepend to the error message

Raises:
AssertionError – if `member` is not included in `container`

```
static assert_is(a: Any, b: Any, message: str | None = None) → None
```

Assert that `id(a)` equals `id(b)`.

Parameters:

- **a** – an object
- **b** – another object
- **message=None** – the message to prepend to the error message

Raises:
AssertionError – if `id(a)` does not equal `id(b)`

```
static assert_is_instance(obj: Any, cls: Type, message: str | None = None) → None
```

Assert that `obj` is an instance of `cls`.

Parameters:

- **obj** – an instance
- **cls** – a class `obj` shall be an instance of
- **message=None** – the message to prepend to the error message

Raises:
AssertionError – if `obj` is not an instance of `cls`.

```
static assert_is_none(obj: Any, message: str | None = None) → None
```

Assert that `obj` is `None`.

Parameters:

- **obj** – an object
- **message=None** – the message to prepend to the error message

Raises:
AssertionError – if `obj` is not `None`

```
static assert_is_not(a: Any, b: Any, message: str | None = None) → None
```

Assert that `id(a)` does not equal `id(b)`.

Parameters:

- **a** – an object
- **b** – another object
- **message=None** – the message to prepend to the error message

Raises:
AssertionError – if `id(a)` equals `id(b)`

```
static assert_is_not_instance(obj: Any, cls: Type, message: str | None = None) → None
```

Assert that `obj` is an instance of `cls`.

Parameters:

- **obj** – an instance
- **cls** – a class `obj` shall be an instance of
- **message=None** – the message to prepend to the error message

Raises:
AssertionError – if `obj` is not an instance of `cls`.

```
static assert_is_not_none(obj: Any, message: str | None = None) → None
```

Assert that `obj` is not `None`.

Parameters:

- **obj** – an object
- **message=None** – the message to prepend to the error message

Raises:
AssertionError – if `obj` is `None`

```
static assert_less(a: Any, b: Any, message: str | None = None) → None
```

Assert that `a` is less than `b`.

Parameters:

- **a** – a comparable object
- **b** – a comparable object
- **message=None** – the message to prepend to the error message

Raises:
AssertionError – if `a` is not less than `b`

```
static assert_less_equal(a: Any, b: Any, message: str | None = None) → None
```

Assert that `a` is less or equal to `b`.

Parameters:

- **a** – a comparable object
- **b** – a comparable object
- **message=None** – the message to prepend to the error message

Raises:
AssertionError – if `a` is not less or equal to `b`

```
static assert_list_equal(a: List, b: List, message: str | None = None) → None
```

Assert that `a` equals `b` and that both are of type `list`.

Parameters:

- **a** – a list
- **b** – a list
- **message=None** – the message to prepend to the error message

Raises:
AssertionError – if `a` and `b` are not equal.

```
static assert_multi_line_equal(a: str, b: str, message: str | None = None) → None
```

Assert that `a` equals `b` and that both are of type `str`.

Parameters:

- **a** – a string
- **b** – a string
- **message=None** – the message to prepend to the error message

Raises:
AssertionError – if `a` and `b` are not equal.

```
static assert_not_almost_equal(a: float, b: float, places: int | None = None, delta:
float | None = None, message: str | None = None) → None
```

Assert that `a` and `b` are not almost equal. Useful to compare floating point numbers. Comparison is realized either using a maximum `delta` or the number of decimal `places`

Parameters:

- **a** – number
- **b** – number
- **places=None** – the number of decimal places for comparison. If `None` `7` decimal places are used.
- **delta=None** – the maximum delta
- **message=None** – the message to prepend to the error message

Raises:
AssertionError – if `a` and `b` are almost equal.

```
static assert_not_equal(a: Any, b: Any, message: str | None = None) → None
```

Assert that `a` does not equal `b`.

Parameters:

- **a** – an object
- **b** – an object
- **message=None** – the message to prepend to the error message

Raises:
AssertionError – if `a` and `b` are equal.

```
static assert_not_in(member: Any, container: Iterable, message: str | None = None) →
None
```

Assert that `container` does not contain `member`.

Parameters:

- **member** – the object that shall not be included in `container`

- **container** – an iterable to search for `member`
- **message=None** – the message to prepend to the error message

Raises:
AssertionError – if `member` is included in `container`

```
static assert_not_is_instance(obj: Any, cls: Type, message: str | None = None) → None
```

Assert that `obj` is an instance of `cls`.

Parameters:

- **obj** – an instance
- **cls** – a class `obj` shall be an instance of
- **message=None** – the message to prepend to the error message

Raises:
AssertionError – if `obj` is not an instance of `cls`.

```
static assert_not_regex(text: str, unexpected_regex: str, message: str | None = None) →
None
```

Assert that `text` does not match regular expression `unexpected_regex`.

Parameters:

- **text** – a text to be matched
- **unexpected_regex** – a regular expression to be used
- **message=None** – the message to prepend to the error message
- **Raises** – AssertionError: if `text` matches regular expression `unexpected_regex`.

```
static assert_raises(expected_exception: Type[BaseException], callable_object: Any |
None = None, *args: Any, **kwargs: Any) → _AssertRaisesContext | None
```

Assert that `expected_exception` is raised. Can be used as a context manager or with a callable object that is run with `*args` and `**kwargs`.

Parameters:

- **expected_exception** – the expected exception that shall be raised
- **callable_object=None** – the callable object if not used as a context manager
- ***args** – variable positional arguments passed to `callable_object`
- ****kwargs** – variable keyword arguments passed to `callable_object`

Returns:
a context manager if `callable_object` is `None` else `None`.

```
static assert_raises_regex(expected_exception: Type[BaseException], expected_regex: str,
callable_object: Any | None = None, *args: Any, **kwargs: Any) → _AssertRaisesContext |
None
```

Assert that `expected_exception` is raised. Can be used as a context manager or with a callable object that is run with `*args` and `**kwargs`.

Parameters:

- **expected_exception** – the expected exception that shall be raised
- **expected_regex** – the regular expression that shall match the stringified representation of the exception
- **callable_object=None** – the callable object if not used as a context manager
- ***args** – variable positional arguments passed to `callable_object`
- ****kwargs** – variable keyword arguments passed to `callable_object`

Returns:
a context manager if `callable_object` is `None` else `None`.

```
static assert_regex(text: str, expected_regex: str, message: str | None = None) → None
```

Assert that `text` matches regular expression `expected_regex`.

Parameters:

- **text** – a text to be matched
- **expected_regex** – a regular expression to be used
- **message=None** – the message to prepend to the error message
- **Raises** – AssertionError: if `text` does not match regular expression `expected_regex`.

```
static assert_sequence_equal(a: Sequence, b: Sequence, message: str | None = None,
sequence_type: Type | None = None) → None
```

Assert that `a` equals `b` and that both are sequences.

Parameters:

- **a** – a sequence
- **b** – a sequence
- **sequence_type=None** – the sequence type to be used (if not `None`)
- **message=None** – the message to prepend to the error message

Raises:
AssertionError – if `a` and `b` are not equal.

```
static assert_set_equal(a: Set, b: Set, message: str | None = None) → None
```

Assert that `a` equals `b` and that both are of type `set`.

Parameters:

- **a** – a set
- **b** – a set
- **message=None** – the message to prepend to the error message

Raises:
AssertionError – if `a` and `b` are not equal.

```
static assert_str_equal(a: str, b: str, message: str | None = None) → None
```

Assert that `a` equals `b` and that both are of type `str`.

Parameters:

- **a** – a string
- **b** – a string
- **message=None** – the message to prepend to the error message

Raises:
AssertionError – if `a` and `b` are not equal.

```
static assert_true(expression: bool, message: str | None = None) → None
```

Assert that `expression` is `True`.

Parameters:

- **expression** – the boolean expression to be validated
- **message=None** – the message to prepend to the error message

Raises:
AssertionError – if `expression` is not `True`

```
static assert_tuple_equal(a: Tuple, b: Tuple, message: str | None = None) → None
```

Assert that `a` equals `b` and that both are of type `tuple`.

Parameters:

- **a** – a list
- **b** – a list
- **message=None** – the message to prepend to the error message

Raises:
AssertionError – if `a` and `b` are not equal.

```
attach_file(filename: str, title: str) → None
```

Attach a file to the current test that is put into the test report.

Parameters:

- **filename** – the filename to be attached
- **title** – the title

```
attach_url(url: str, title: str) → None
```

Attach an url to the current test that is put into the test report. This results in an external link and should be used for huge files.

Parameters:

- **url** – the url to be attached
- **title** – the title

```
delay(duration: float) → None
```

Delay execution for a given duration and print progress.

Parameters:
duration – sleep duration

```
expect(expected_value: Any, observed_value: Any, error_message: str | None = None) → None
```

Expect that `expectedValue` and `observedValue` are the same. If `expectedValue` and `observedValue` differ an `AssertionError` is raised.

Parameters:

- **expected_value** – the expected value.
- **observed_value** – the observed value that is compared to `expectedValue`.
- **errorMessage=None** – an optional message.

```
expect_step(title: str, expected_value: Any, observed_value: Any, error_message: str |
None = None) → None
```

Creates a test step in test report and on stdout using `title`. Expect that *expectedValue* and *observedValue* are the same. If `expectedValue` and `observedValue` differ an `AssertionError` is raised.

Parameters:

- **title** – the step's title.
- **expected_value** – the value that is expected.
- **observed_value** – the current observed value that is compared to `expectedValue`.
- **errorMessage=None** – an optional message.

```
run_background(func: Callable[[...], Any], name: str | None = None, stop:
Callable[[...], bool] | None = None, force_stop: bool = True, join_timeout: float = 1.0,
args: Tuple[Any] | None = None, kwargs: Dict[str, Any] | None = None) → Callable[[], None]
```

With this method you can run another method in background.

Parameters:

- **func** – the method to be run in background.
- **name=None** – a name for the background task. Default: `None`. If *name* is `None` *func.__name__* is used.
- **stop=None** – callable to stop the thread
- **force_stop=True** – force the thread to stop when leaving its scope (can impact performance)
- **join_timeout=1** – the timeout to be used when calling `join` on the thread.
- **args=None** – a tuple of positional arguments that are passed to the background task when it is called.
- **kwargs=None** – a dictionary of keyword arguments that are passed to the background task when it is called.

Returns:
a callable object is returned that stops

execution when called.

Return type:
stop-trigger

```
run_periodic(func: Callable[[...], Any], period: float, maximum_period: float | None =
None, name: str | None = None, raise_exception: bool = True, args: Tuple[Any] | None =
None, kwargs: Dict[str, Any] | None = None) → Callable[[], None]
```

With this method you can run another method periodically in background with a given period.

Parameters:

- **func** – the method to be called periodically in background.
- **period** – the period in second.
- **maximum_period=None** – if set to a float >= `period` `func` may take up to `maximum_period` time without raising an exception. A warning is printed out to stdout instead.
- **name=None** – a name for the background task.
- **raise_exceptions=True** – if set to `True` exceptions are put into the exception queue to let a test fail if a background thread fails.
- **args=None** – a tuple of positional arguments that are passed to the background task when it is called.
- **kwargs=None** – a dictionary of keyword arguments that are passed to the background task when it is called.

Returns:
a callable object is returned that stops

execution when called.

Return type:
stop-trigger

```
set_metadata(name: str, value: Any) → None
```

Set metadata for a running test.

Parameters:

- **name** – the name of the metadata
- **value** – the value of the metadata (`value` is casted to a string automatically)

Raises:
AssertionError – if `name` was already set to non accidentally overwrite existing metadata

```
set_output_capture_enable(enabled: bool = True) → None
```

Enables or disables capturing of stdout and stderr for later use in test reports.

Parameters:
enabled=True – the new enabled state

```
set_up() → None
```

This method is called from test runner before a test is executed to create the test-fixtures.

```
classmethod set_up_class() → None
```

This method is called for each class instance.

```
skip_step(message: str) → None
```

Skip the current test step.

```
skip_test(message: str) → None
```

Skip the current test.

```
async sleep(duration: float) → None
```

Delay execution (async) for a given duration and print progress.

Parameters:
duration – sleep duration

```
step(title: str, expected_result: str | None = None, *args: Any, **kwargs: Any) →
TestStep
```

Run a test step that is documented in the test report.

Parameters:

- **title** – the step's title.
- ***args** – a tuple of positional arguments for the step's context.
- ****kwargs** – a dictionary of keyword arguments for the step's context.

```
stop_thread(name_or_function: str | Callable) → int
```

This method stops a specific thread with the name or function described by `name_or_function` by calling `join` with join timeout supplied by `run_periodic` or `run_background` or on it. It does not set a stop condition so the thread must end and must not include an endless loop. If the thread is still alive after the first join messages are printed to inform the user.

Parameters:
name_or_function – the name or the function (reference) of the thread to be stopped.
Returns:
the number of stopped threads.
Return type:
int
Raises:
Exception – if the thread was not found

```
tear_down() → None
```

This method is called from test runner after a test was executed regardless of its result.

This method shall destroy all used fixtures.

```
classmethod tear_down_class() → None
```

This method is called for each class instance.

Fixtures

Fixtures provide data, objects or services for tests. They are automatically initialized and uninitialized by the test runner.

Fixtures have a scope:

- `'test'`: Fixture is initialized and uninitialized for every single test. Smallest scope.

- `'class'`: Fixture is initialized when a class holding tests is run for the first time, and uninitialized after all tests of the are run.
- `'module'`: Fixture is initialized once for all tests in a module.
- `'session'`: Fixture is initialized for the whole session. Greatest scope.

Fixtures are implemented as python functions returning an object or python generators yielding a single object. Python generators offer set up and tear down code while python function fixture only offer set up code.

To use a fixture in a test, simply add a parameter with the fixture's name to the test. The yielded object is passed to the test when it is executed by the test runner.

Fixtures are collected automatically by the test runner by searching the test specifiers.

To create a fixture decorate it with `htf.fixture`.

```
@htf.fixture('test')
def server() -> Generator["Server", None, None]:
    server = Server()
    yield server
    server.stop()

# pass a parameter with the fixture's name to use the fixture
def test_server(server):
    server.handle_request()
```

Fixtures can also depend on other fixtures. To create a dependency simply add a parameter to the fixture like you would for a test.

```
@htf.fixture('test')
def client(server):
    return Client()

def test_client(client, server):
    server.run()
    client.connect()
```

Circular dependencies are detected and raise an exception.

Requested fixtures must have the same or a greater scope than the requesting fixture. I.e. a fixture with scope 'test' can request fixtures with all other scopes, but a fixture with scope 'session' can only request other fixtures with 'session' scope.

You can change the fixture name by setting the `name` parameter.

Generally fixtures are only called when specifically requested by tests or other fixtures. For auxillary fixtures which require no direct interaction, you can set the `auto` parameter to `True`. In this case they are set up and torn down when their scope is entered or left.

Fixtures can be async, too.

```
@htf.fixture('test')
async def async_fixture() -> AsyncGenerator["Server", None]:
    server = await Server.create()
    yield server
    await server.stop()
```

Creating Fixtures

To create fixtures develop them using the `htf.fixture` decorator.

Using Fixtures

To use fixtures, add the sources containing the fixtures as test specifier to the `htf` command line utility or `htf.main`. The fixtures are collected automatically.

Fixture Decorator

The `htf.fixture` decorator is used to create fixtures.

```
htf.fixture(scope: str, name: str | None = None, auto: bool = False) → Callable[[...], Any]
```

Decorator to mark a function as a fixture.

Parameters:

- **scope** – the scope determining the life-time of the fixture. Choose out of ‘session’, ‘module’, ‘class’ and ‘test’.
- **name=None** – the name to be used for the fixture
- **auto=False** – automatically call the fixture when its scope is entered, instead of when requested

Built-in Fixtures

htf is shipped with many built-in fixtures for different use cases.

Assertions (assertions)

`assertions` lets you easily do assertions. The fixture is `htf.assertions`. The scope is `'session'`.

```
def test_with_assertions(assertions):
    """
    Args:
        assertions (htf.assertions): the assertions fixture
    """
    assertions.assert_true(True)
```

File and URL Attachments (attachments)

`htf.fixtures.attachments` lets you attach files and URLs to a test report. The scope is `'test'`.

```
def test_attach_file(attachments):
    """
    Args:
        attachments (htf.fixtures.attachments): the attachments fixture
    """
    attachments.attach_file("example.jpg", "an example image attached to a report")
```

Attaching files as bytes

```
def test_attach_file_as_bytes(attachments):
    """
    Args:
        attachments (htf.fixtures.attachments): the attachments fixture
    """
    filename = "example.png"
    mime_type = "image/png"
    with open(filename, "rb") as f:
        data_bytes = f.read()
        attachments.attach_bytes("Example", data_bytes, filename, mime_type)
```

Attaching a URL

```
def test_attach_url(attachments):
    """
    Args:
        attachments (htf.fixtures.attachments): the attachments fixture
    """
    attachments.attach_url("https://hilster.io", "an example URL attached to a report")
```

```
class htf.fixtures.attachments(result: TestResult)
```

Attachments to the test report. Scope is `'test'`.

```
attach_bytes(title: str, data_bytes: bytes, filename: str, mime_type: str) → None
```

Accepts bytes and mime type and converts them to a data url and attaches it to the result.

Parameters:

- **title** – the title
- **data_bytes** – the bytes to attach
- **filename** – the file name
- **mime_type** – MIME type of the data bytes

```
attach_file(filename: str, title: str) → None
```

Attach a file to the current test that is put into the test report.

Parameters:

- **filename** – the filename to be attached
- **title** – the title

```
attach_url(url: str, title: str) → None
```

Attach an url to the current test that is put into the test report. This results in an external link and should be used for huge files.

Parameters:

- **url** – the url to be attached
- **title** – the title

```
set_maximum_attachment_size(size: int) → None
```

Set the maximum attachment size to `size` bytes.

Parameters:
size – the maximum attachment size in bytes. Default ist 10 MB.

To increase the maximum attachment size simply create a new fixture with the maximum size set to the desired value:

```
@htf.fixture('test')
def big_attachments(attachments):
    attachments.set_maximum_attachment_size(100*1024*1024)  # 100 MB
    yield attachments
```

Context (context)

The `htf.fixtures.context` is used to share data between steps within a behavior driven test. The scope is `'test'`.

```
class htf.fixtures.context
```

A context fixture used to share context data in behavior driven steps.

```
@htf.given("the DUT is up and running")
def up_and_running(context):
    context.dut = DUT()
```

```
@htf.when("button is pressed")
def button_is_pressed(context):
    context.dut.press_button()

@htf.then(r"the button state shall be '([a-z]+)'")
def button_state(pressed, context):
    htf.assert_equal(context.dut.get_button_state(), pressed)
```

Delay Functions (delay)

`htf.fixtures.delay` lets you delay tests. The remaining delay is printed to the terminal. `htf.fixtures.delay` is callable. The scope is `'session'`.

```
def test_with_delay(delay):
    """
    Args:
        delay (htf.fixtures.delay): the delay fixture
    """
    delay(5)
```

```
class htf.fixtures.delay
```

Delay execution for a given duration and print progress. Scope is `'session'`.

Parameters:
duration – delay duration in seconds

Sleep Functions (async) (sleep)

`htf.fixtures.sleep` lets you delay tests. The remaining delay is printed to the terminal. `htf.fixtures.sleep` is callable. The scope is `'session'`.

```
async def test_with_sleep(desleeplay):
    """
    Args:
        sleep (htf.fixtures.sleep): the sleep fixture
    """
    await sleep(5)
```

```
class htf.fixtures.sleep
```

Delay execution for a given duration and print progress. Used in async context only. Scope is `'session'`.

Parameters:
duration – delay duration in seconds

Interactive Testing (interaction)

The `htf.fixtures.interaction` fixture is documented in the Interactive Testing section.

Issue Tracking (jira)

The usage of the `htf.fixtures.jira` fixture is documented in the JIRA (Atlassian) section.

Append Metadata to Test Reports (metadata)

`htf.fixtures.metadata` lets you add metadata to tests. `htf.fixtures.metadata` works like a `dict` but also support setters and getters. The scope is `'test'`.

```
def test_with_metadata(metadata):
    """
    Args:
        metadata (htf.fixtures.metadata): the metadata fixture
    """
    metadata.set("key", "value")
    metadata["Date"] = datetime.now()
```

```
class htf.fixtures.metadata(result: TestResult)
```

Set metadata in test report. Scope is `'test'`.

```
get(name: str) → Any
```

Get metadata for name.

Parameters:
name – metadata name
Returns:
the value
Return type:
object

```
set(name: str, value: Any) → None
```

Set a metadata name to a value.

Parameters:

- **name** – metadata name
- **value** – metadata value

Access Settings (settings)

`Settings` lets you easily access settings in a test. The returned object is an instance of `htf.Settings`. The scope is `'session'`.

```
def test_with_settings(settings):
    """
    Args:
        settings (htf.fixtures.settings): the settings fixture
    """
    print(settings.example_setting)
```

Access Testrun Parameters (parameters)

`Parameters` lets you easily access test run parameters in a test. The returned object is an instance of a read-only dict like object. The scope is `'session'`.

```
def test_parameters(parameters):
    """
    Args:
        settings (htf.fixtures.parameters): the parameters fixture
    """
    print(parameters['name'])

   # htf --parameter name=foobar
   # htf.main(parameters=dict(name="foobar"))
```

Parameters can also be used to control the behavior of other fixtures.

```
@htf.fixture(scope="test")
def io(parameters):
    if parameters.get('io_enable', default=False):
        yield IO(parameters['io_settings'])
    else:
        yield SimulatedIO(parameters['io_settings'])
```

```
class htf.fixtures.Parameters(data: Dict[Any, Any])
```

Access parameters in test report. Scope is `'session'`. Is instantiated automatically.

Structure Tests (step)

`htf.fixtures.step` lets you separate your test into steps. The scope is `'test'`.

```
def test_with_step(step):
    """
    Args:
        step (htf.fixtures.step): the step fixture
    """
    with step("First step"):
        htf.assert_true(True)

    # steps can be nested, too
    with step("Outer step"):
        with step("Inner step"):
            htf.assert_true(True)

    # steps can have an expected result
    with step("Succeeding step", expected_result="this step succeeds"):
        htf.assert_true(True)
```

You can also add additional data to steps that will be put into the test report.

```
def test_with_additional_step_data(step):
    """
    Args:
        step (htf.fixtures.step): the step fixture
    """
    with step("First step", 1, 2, 3, step_id=100):
        htf.assert_true(True)
```

To skip a step run

```
def test_with_skipped_step(step):
    """
    Args:
        step (htf.fixtures.step): the step fixture
    """
    with step("Skipped step"):
        step.skip("This step is skipped.")
```

`htf.fixtures.step` supports expected and actual results, too.

```
def test_with_expected_and_actual_result(step):
    """
    Args:
        step (htf.fixtures.step): the step fixture
    """
    with step("Step with expected and actual result", expected_result="The expected result") as
current_step:
        current_step.set_actual_result("the actual result")
```

`htf.fixtures.step` can be used as a `dict` to add data to the test result at runtime. The default contents are read-only.

```
def test_with_expected_and_actual_result(step):
    """
    Args:
        step (htf.fixtures.step): the step fixture
    """
    with step("Step with expected and actual result", expected_result="The expected result") as
current_step:
        current_step["actual_result"] = "the actual result"
```

```
class htf.fixtures.step(result: TestResult)
```

Run a test step that is documented in the test report. Scope is `'test'`.

Parameters:

- **title** – the step's title.
- **callable_obj=None** – a callable object that is called within the step or `None`.
- ***args** – a tuple of positional arguments for the step's context.
- ****kwargs** – a dictionary of keyword arguments for the step's context.

```
skip(reason: str | None = None) → None
```

Skip a step.

Parameters:
reason=None – the reason for the skipped step
Raises:
htf.SkipStep –

Test Information (test)

`htf.fixtures.test` gives you access to information about the current test. The scope is `'test'`.

```
def test_info(test):
    """
    Args:
        test (htf.fixtures.test): the test fixture
    """
    print("Test function name:", test.name)
    print("Test class name:", test.class_name)
    print("Test module:", test.module)
    print("Docstring:", test.doc)
    print("Tags:", test.tags)
    print("Current stdout:", test.stdout)
    print("Current stderr:", test.stderr)
    print("Current result:", test.result)  # None
```

The properties `test.result`, `test.was_successful`, `test.was_not_successful`, `test.was_failure`, `test.was_error`, `test.exception_type`, `test.exception_value` and `test.exception_traceback` are only available after the test was run in the context of another fixture using the `test` fixture.

Thus, it is possible to add actions in fixtures depending on the test's result.

```
@htf.fixture(scope="test", auto=True)
def after_failed_test(test):
    yield

    if test.was_not_successful:
        print(f"The test {test.name} was not successful! It failed with
{test.exception_type.__class__.__name__}: '{test.exception_value}'")

def test_failure(test):
    assert False, "This test fails"
```

```
class htf.fixtures.test(result: TestResult)
```

Information about the running test. Scope is `'test'`.

Feature Information (feature)

`htf.fixtures.feature` gives you access to information about the current feature running in a behavior driven test. The scope is `'test'`.

```
@htf.given("when I would like to see feature information")
def given_feature(feature):
    """
    Args:
        test (htf.fixtures.feature): the feature fixture
    """
    print("Feature name:", feature.name)
    print("Feature doc:", feature.doc)
    print("Feature filename:", feature.filename)
```

```
class htf.fixtures.feature(result: TestResult)
```

Information about the running feature in behavior driven testing. Scope is `'test'`.

Scenario Information (scenario)

`htf.fixtures.scenario` gives you access to information about the current scenario running in a behavior driven test. The scope is `'test'`.

```
@htf.given("when I would like to see scenario information")
def given_feature(scenario):
    """
    Args:
        test (htf.fixtures.scenario): the scenario fixture
    """
    print("Scenario name:", scenario.name)
```

```
class htf.fixtures.scenario(result: TestResult)
```

Information about the running scenario in behavior driven testing. Scope is `'test'`.

Statistics (statistics)

`htf.fixtures.statistics` gives you statistics about the current test session. The scope is `'session'`.

```
def test_statistics(statistics):
    """
    Args:
        statistics (htf.fixtures.statistics): the statistics fixture
    """
    print("Total number of tests:", statistics.number_of_tests)
    print("Tests run so far:", statistics.tests_run)
    print("Percent of tests finished:", statistics.done_percent)
    print("Successes:", statistics.successes)
    print("Failures:", statistics.failures)
    print("Errors:", statistics.errors)
    print("Skipped:", statistics.skipped)
    print("Percent of successes:", statistics.success_percent)
    print("Percent of failures:", statistics.failure_percent)
    print("Percent of errors:", statistics.error_percent)
    print("Percent of skipped:", statistics.skipped_percent)
```

```
class htf.fixtures.statistics(statistics_provider: statistics_provider)
```

Statistics about the test session. Scope is `'session'`.

Run Threads (threads)

`htf.fixtures.threads` lets you start threads that are stopped automatically. You can start continuously running threads and periodically executed threads. The scope is `'test'`. All started threads are automatically stopped after the starting test ends. You do not need to worry about stopping threads yourself.

```
def test_with_background_thread(threads):
    """
    Args:
```

```
        threads (htf.fixtures.threads): the threads fixture
    """
    def background_thread():
        while True:
            print("running in background")

    threads.run_background(background_thread)

def test_with_periodic_thread(threads):
    """
    Args:
        threads (htf.fixtures.threads): the threads fixture
    """
    def periodic_thread():
        print("running periodically in background")

    threads.run_periodic(periodic_thread, period=1.0)
    time.sleep(5)
```

Automatic stoppable threads are instrumented to be stoppable under all circumstances. Thus the performance may be impacted but `while True` loops are allowed in these threads, the development is very easy and you do not need any overhead to stop the thread. If you need more performance for background threads you have to make your threads stoppable from the outside and not use `while True` loops.

```
def test_stoppable_thread(threads):
    # create an event to stop the thread
    stop_condition = threading.Event()

    def background_thread():
        while not stop_condition.is_set():
            print("running ..")
            time.sleep(.5)

    # normally started threads that is stopped automatically with reduced performance
    threads.run_background(background_thread)

    # high performance background thread that
    stop = threads.run_background(background_thread, stop=stop_condition.set, force_stop=False)

    # wait
    time.sleep(2.0)

    # stop the thread explicitly
    stop()
```

```
class htf.fixtures.threads
```

Fixture for threads with scope ‘test’ that are stopped automatically and can run in background and periodically.

```
run_background(func: Callable[[...], Any], name: str | None = None, stop:
Callable[[...], bool] | None = None, force_stop: bool = True, join_timeout: float = 1.0,
args: Tuple[Any] | None = None, kwargs: Dict[str, Any] | None = None) → Callable[[], None]
```

With this method you can run another method in background.

Parameters:

- **func** – the method to be run in background.
- **name=None** – a name for the background task. Default: `None`. If *name* is `None` *func.__name__* is used.
- **stop=None** – callable to stop the thread
- **force_stop=True** – force the thread to stop when leaving its scope (can impact performance)
- **join_timeout=1** – the timeout to be used when calling `join` on the thread.
- **args=None** – a tuple of positional arguments that are passed to the background task when it is called.
- **kwargs=None** – a dictionary of keyword arguments that are passed to the background task when it is called.

Returns:
a callable object is returned that stops

execution when called.

Return type:
stop-trigger

```
run_periodic(func: Callable[[...], Any], period: float, maximum_period: float | None =
None, name: str | None = None, raise_exception: bool = True, args: Tuple[Any] | None =
None, kwargs: Dict[str, Any] | None = None) → Callable[[], None]
```

With this method you can run another method periodically in background with a given period.

Parameters:

- **func** – the method to be called periodically in background.
- **period** – the period in second.
- **maximum_period=None** – if set to a float >= `period` `func` may take up to `maximum_period` time without raising an exception. A warning is printed out to stdout instead.
- **name=None** – a name for the background task.
- **raise_exceptions=True** – if set to `True` exceptions are put into the exception queue to let a test fail if a background thread fails.
- **args=None** – a tuple of positional arguments that are passed to the background task when it is called.
- **kwargs=None** – a dictionary of keyword arguments that are passed to the background task when it is called.

Returns:
a callable object is returned that stops

execution when called.

Return type:
stop-trigger

```
stop() → None
```

This method stops all background threads by calling `thread.join()` until it is not alive anymore.

```
stop_thread(name_or_function: str | Callable) → int
```

This method stops a specific thread with the name or function described by `name_or_function` by calling `join` with join timeout supplied by `run_periodic` or `run_background` or on it. It does not set a stop condition so the thread must end and must not include an endless loop. If the thread is still alive after the first join messages are printed to inform the user.

Parameters:
name_or_function – the name or the function (reference) of the thread to be stopped.
Returns:
the number of stopped threads.
Return type:
int
Raises:
Exception – if the thread was not found

Run Session Threads (session_threads)

Like `htf.fixtures.threads` but with scope `'session'`.

Run Processes (processes)

`htf.fixtures.processes` lets you start processes that are stopped automatically. You can start single background processes and process pools. It is based on `multiprocessing`. The scope is `'test'`. All started processes are automatically stopped after the starting test ends. You do not need to worry about stopping processes yourself.

Create a single background process:

```
def test_process_stopping(processes):
    """
    Test a stopping background process.

    Args:
        processes (htf.fixtures.processes): the processes fixture
    """
    def process(*what):
        print("process is running ..")
        for i in range(2):
            print(" ".join(what))
            time.sleep(1.0)

    processes.run(target=process, args=("a", "b"))
    time.sleep(3.0)
```

Create a pool and run tasks in parallel:

```
def square(x):
    return x**2

def test_pool(processes):
    """
    Test processes fixture's pool.

    Args:
        processes (htf.fixtures.processes): the processes fixture
    """
    pool = processes.pool(processes=2)
    print(pool.map(square, range(10)))
    time.sleep(1.0)
```

```
class htf.fixtures.processes
```

Fixture for background processes with scope `'test'` that are stopped automatically. Uses `multiprocessing`.

```
pool(processes: int | None = None, initializer: Callable[[...], Any] | None = None,
initargs: Iterable[Any] = (), maxtasksperchild: int | None = None, timeout: float = 1.0) →
multiprocessing.pool.Pool
```

Create a pool to run tasks in parallel.

Parameters:

- **processes=None** – the number of child processes to be started.
- **initializer=None** – f initializer is not None then each worker process will call `initializer(*initargs)` when it starts.
- **initargs=()** – arguments for `initializer`.
- **maxtasksperchild=None** – the maximum number of tasks per child process.
- **timeout=1.0** – the timeout for joining the pool process.

Returns:
the pool

```
run(group: None = None, target: Callable[[...], Any] | None = None, name: str | None =
None, args: Iterable[Any] = (), kwargs: Dict[str, Any] | None = None, daemon: bool | None
= None, timeout: float = 1.0) → Process
```

Run a background process.

Parameters:

- **group=None** – the group

- **target=None** – A callable to be run in background. Must be pickleable.
- **name=None** – the name of the background process.
- **args=()** – the positional arguments passed to the background process callable.
- **kwargs=None** – the keyword arguments passed to the background process callable.
- **daemon=None** – if set to `True` the child process is terminated if the parent process ends.
- **timeout=1.0** – the timeout for joining, terminating and killing the process.

Returns:
the process

Run Session Processes (session_processes)

Like `htf.fixtures.processes` but with scope `'session'`.

Type Hints for fixtures

To be able to use code completion in you IDE add type hints or docstrings to your tests so that the IDE is able to find the right fixture.

```
# type hint:
def test_step(step : htf.fixtures.step):
    with step("A step"):
        pass

# docstring:
def test_step(step):
    """
    This test ...

    Args:
        step (htf.fixtures.step): the step fixture
    """
    with step("A step"):
        pass
```

Example: Cache Fixture

Assume you want to cache data over multiple test runs to reduce the runtime. You could create a cache fixture.

```
import json
# cache fixture
@htf.fixture('session')
def cache():
    # set up
    filename = "cache.json"
    try:
        with open(filename, "r") as fp:
            data = json.load(fp)
    except FileNotFoundError:
        with open(filename, "w") as fp:
```

```
            json.dump({}, fp)
            print("Created cache file '{}'".format(filename))
        data = {}

    yield data

    # tear down
    with open(filename, "w") as fp:
        json.dump(data, fp)
        print("Wrote cache file '{}'".format(filename))

# test using cache fixture
def test_cache(cache):
    try:
        # count up test run number
        cache["#"] += 1
    except KeyError:
        cache["#"] = 1

    print("This is test run {}".format(cache["#"]))
```

Tagging Fixtures

Fixtures can also be tagged. Thus it is easy to select a set of fixture with a tag expression.

For example you can create fixtures for simulated and hardware in the loop devices with different tags and select a group to run the same tests with and without hardware.

`htf` support `-F <expression>` and `--fixture-tags=<expression>`. Unlike selecting tests by tags all untagged fixtures are included in the result. So if you use fixture tags they will only be used to filter actually tagged fixtures.

Example:

```
class Device:
    pass

@htf.tags("simulation")
@htf.fixture('test', name="device")
def device_simulation():
    print("simulated device")
    yield Device()

@htf.tags("hardware")
@htf.fixture('test', name="device")
def device_hardware():
    print("hardware device")
    yield Device()

def test_device(device):
    pass
```

```
if __name__ == "__main__":
    htf.main(fixture_tags="hardware")
    # $ htf --fixture-tags=hardware
```

Accessing Fixtures directly

You might need to access one fixture in a location where it is not already set up. This is useful for fixtures that are not part of the argument list of the test function. To do that, you can use `htf.get_fixture` (async variant) or `htf.get_fixture_sync` (sync variant).

If the fixture was not instantiated before, then it will be instantiated as soon as the upper functions are called.

For async (coroutine) fixtures, the following example shows the behavior.

```
@htf.fixture('test')
async def example_fixture():
    yield "Example"

async def test_device():
    fixture = await htf.get_fixture("example_fixture")
```

In case you don't want to use coroutines, it is still possible to use the sync variant.

```
@htf.fixture('test')
def example_fixture():
    yield "Example"

def test_device():
    fixture = htf.get_fixture_sync("example_fixture")
```

Note

`htf.get_fixture_sync` will raise an exception when trying to instantiate an async fixture. It will however return already instantiated fixtures regardless of its type.

```
async htf.get_fixture(name: str) → Any
```

Returns a fixture object as identified by the name parameter. If a fixture requires other fixtures, they will be instantiated, if necessary. This is the async variant which returns a coroutine, so ideal for async fixtures.

Parameters:
name – name of the requested fixture
Returns:
fixture instance

Raises:
Exception – if a circular dependency is detected during resolution

```
htf.get_fixture_sync(name: str) → Any
```

Returns a fixture object as identified by the name parameter. If a fixture requires other fixtures, they will be instantiated, if necessary. This is the sync variant which returns the fixture instance.

Parameters:
name – name of the requested fixture
Returns:
fixture instance
Raises:

- **Exception** – if a circular dependency is detected during resolution
- **TypeError** – if the instantiated fixture is a coroutine

Assertions

Assertions are used to assert conditions of your tests. With assertions the actual testing is realized.

Assert Statement

The easiest way to assert a statement is to use the `assert` statement.

```
def test_with_assert():
    assert True, "This is the assertions failure message"
```

Built-in Assertions

To write tests with finegrained assertions you can use the built-in assertions.

All specialized assertions can be used via the module `htf.assertions` or the `assertions` fixture.

```
def test_with_assertions_fixture(assertions):
    assertions.assert_true(True, "This is the assertions failure message")
    assertions.assert_almost_equal(1.00, 1.01, places=2)
    # etc.

def test_with_assertions_module():
    htf.assertions.assert_true(True, "This is the assertions failure message")
    htf.assertions.assert_almost_equal(1.00, 1.01, places=2)
```

```
htf.assertions.assert_almost_equal(a: float, b: float, places: int | None = None, delta:
float | None = None, message: str | None = None) → None
```

Assert that `a` and `b` are almost equal. Useful to compare floating point numbers. Comparison is realized either using a maximum `delta` or the number of decimal `places`

Parameters:

- **a** – number
- **b** – number
- **places=None** – the number of decimal places for comparison. If `None` `7` decimal places are used.
- **delta=None** – the maximum delta
- **message** – the message to prepend to the error message

Raises:
AssertionError – if `a` and `b` are not almost equal

```
htf.assertions.assert_dict_equal(a: Dict, b: Dict, message: str | None = None) → None
```

Assert that `a` equals `b` and that both are of type `dict`.

Parameters:

- **a** – a dict
- **b** – a dict
- **message** – the message to prepend to the error message

Raises:
AssertionError – if `a` and `b` are not equal

```
htf.assertions.assert_equal(a: Any, b: Any, message: str | None = None) → None
```

Assert that `a` equals `b`. Tries to find a registered equality asserter and uses the base assert if no special assert is registered.

Parameters:

- **a** – an object
- **b** – an object
- **message** – the message to prepend to the error message

Raises:
AssertionError – if `a` and `b` are not equal

```
htf.assertions.assert_false(expression: bool, message: str | None = None) → None
```

Assert that `expression` is `False`.

Parameters:

- **expression** – the boolean expression to be validated

- **message** – the message to prepend to the error message

Raises:
AssertionError – if `expression` is not `False`

```
htf.assertions.assert_greater(a: Any, b: Any, message: str | None = None) → None
```

Assert that `a` is greater than `b`.

Parameters:

- **a** – a comparable object
- **b** – a comparable object
- **message** – the message to prepend to the error message

Raises:
AssertionError – if `a` is not greater than `b`

```
htf.assertions.assert_greater_equal(a: Any, b: Any, message: str | None = None) → None
```

Assert that `a` is greater or equal to `b`.

Parameters:

- **a** – a comparable object
- **b** – a comparable object
- **message** – the message to prepend to the error message

Raises:
AssertionError – if `a` is not greater or equal to `b`

```
htf.assertions.assert_in(member: Any, container: Iterable, message: str | None = None) →
None
```

Assert that `container` contains `member`.

Parameters:

- **member** – the object that shall be included in `container`
- **container** – an iterable to search for `member`
- **message** – the message to prepend to the error message

Raises:
AssertionError – if `member` is not included in `container`

```
htf.assertions.assert_is(a: Any, b: Any, message: str | None = None) → None
```

Assert that `id(a)` equals `id(b)`.

Parameters:

- **a** – an object

- **b** – another object
- **message** – the message to prepend to the error message

Raises:
AssertionError – if `id(a)` does not equal `id(b)`

```
htf.assertions.assert_is_instance(obj: Any, cls: Type, message: str | None = None) → None
```

Assert that `obj` is an instance of `cls`.

Parameters:

- **obj** – an instance
- **cls** – a class `obj` shall be an instance of
- **message** – the message to prepend to the error message

Raises:
AssertionError – if `obj` is not an instance of `cls`

```
htf.assertions.assert_is_none(obj: Any, message: str | None = None) → None
```

Assert that `obj` is `None`.

Parameters:

- **obj** – an object
- **message** – the message to prepend to the error message

Raises:
AssertionError – if `obj` is not `None`

```
htf.assertions.assert_is_not(a: Any, b: Any, message: str | None = None) → None
```

Assert that `id(a)` does not equal `id(b)`.

Parameters:

- **a** – an object
- **b** – another object
- **message** – the message to prepend to the error message

Raises:
AssertionError – if `id(a)` equals `id(b)`

```
htf.assertions.assert_is_not_instance(obj: Any, cls: Type, message: str | None = None) →
None
```

Assert that `obj` is not an instance of `cls`.

Parameters:

- **obj** – an instance

- **cls** – a class `obj` shall not be an instance of
- **message** – the message to prepend to the error message

Raises:
AssertionError – if `obj` is an instance of `cls`

```
htf.assertions.assert_is_not_none(obj: Any, message: str | None = None) → None
```

Assert that `obj` is not `None`.

Parameters:

- **obj** – an object
- **message** – the message to prepend to the error message

Raises:
AssertionError – if `obj` is `None`

```
htf.assertions.assert_less(a: Any, b: Any, message: str | None = None) → None
```

Assert that `a` is less than `b`.

Parameters:

- **a** – a comparable object
- **b** – a comparable object
- **message** – the message to prepend to the error message

Raises:
AssertionError – if `a` is not less than `b`

```
htf.assertions.assert_less_equal(a: Any, b: Any, message: str | None = None) → None
```

Assert that `a` is less or equal to `b`.

Parameters:

- **a** – a comparable object
- **b** – a comparable object
- **message** – the message to prepend to the error message

Raises:
AssertionError – if `a` is not less or equal to `b`

```
htf.assertions.assert_list_equal(a: List, b: List, message: str | None = None) → None
```

Assert that `a` equals `b` and that both are of type `list`.

Parameters:

- **a** – a list
- **b** – a list

- **message** – the message to prepend to the error message

Raises:
AssertionError – if `a` and `b` are not equal or not lists

```
htf.assertions.assert_multi_line_equal(a: str, b: str, message: str | None = None) → None
```

Assert that `a` equals `b` and that both are of type `str`.

Parameters:

- **a** – a string
- **b** – a string
- **message** – the message to prepend to the error message

Raises:
AssertionError – if `a` and `b` are not equal or not strings

```
htf.assertions.assert_not_almost_equal(a: float, b: float, places: int | None = None,
delta: float | None = None, message: str | None = None) → None
```

Assert that `a` and `b` are not almost equal. Useful to compare floating point numbers. Comparison is realized either using a maximum `delta` or the number of decimal `places`

Parameters:

- **a** – number
- **b** – number
- **places=None** – the number of decimal places for comparison. If `None` `7` decimal places are used.
- **delta=None** – the maximum delta
- **message** – the message to prepend to the error message

Raises:
AssertionError – if `a` and `b` are almost equal

```
htf.assertions.assert_not_equal(a: Any, b: Any, message: str | None = None) → None
```

Assert that `a` does not equal `b`.

Parameters:

- **a** – an object
- **b** – an object
- **message** – the message to prepend to the error message

Raises:
AssertionError – if `a` and `b` are equal

```
htf.assertions.assert_not_in(member: Any, container: Iterable, message: str | None = None) →
None
```

Assert that `container` does not contain `member`.

Parameters:

- **member** – the object that shall not be included in `container`
- **container** – an iterable to search for `member`
- **message** – the message to prepend to the error message

Raises:
AssertionError – if `member` is included in `container`

```
htf.assertions.assert_not_is_instance(obj: Any, cls: Type, message: str | None = None) →
None
```

Assert that `obj` is not an instance of `cls`.

Parameters:

- **obj** – an instance
- **cls** – a class `obj` shall not be an instance of
- **message** – the message to prepend to the error message

Raises:
AssertionError – if `obj` is an instance of `cls`

```
htf.assertions.assert_not_regex(text: str, unexpected_regex: str,
message: str | None = None) → None
```

Assert that `text` does not match regular expression `unexpected_regex`.

Parameters:

- **text** – a text to be matched
- **unexpected_regex** – a regular expression to be used
- **message** – the message to prepend to the error message

Raises:
AssertionError – if `text` matches regular expression `unexpected_regex`

```
htf.assertions.assert_raises(expected_exception: Type[BaseException], callable_object: Any |
None = None, *args: Any, **kwargs: Any) → _AssertRaisesContext | None
```

Assert that `expected_exception` is raised. Can be used as a context manager or with a callable object that is run with `*args` and `**kwargs`.

Parameters:

- **expected_exception** – the expected exception that shall be raised
- **callable_object=None** – the callable object if not used as a context manager
- ***args** – variable positional arguments passed to `callable_object`
- ****kwargs** – variable keyword arguments passed to `callable_object`

Returns:
a context manager if `callable_object` is `None` else `None`.
Raises:
AssertionError – if `expected_exception` is not raised

```
htf.assertions.assert_raises_regex(expected_exception: Type[BaseException], expected_regex:
str, callable_object: Any | None = None, *args: Any, **kwargs: Any) → _AssertRaisesContext |
None
```

Assert that `expected_exception` is raised. Can be used as a context manager or with a callable object that is run with `*args` and `**kwargs`.

Parameters:

- **expected_exception** – the expected exception that shall be raised
- **expected_regex** – the regular expression that shall match the stringified representation of the exception
- **callable_object=None** – the callable object if not used as a context manager
- ***args** – variable positional arguments passed to `callable_object`
- ****kwargs** – variable keyword arguments passed to `callable_object`

Returns:
a context manager if `callable_object` is `None` else `None`.
Raises:
AssertionError – if `expected_exception` is not raised or does not match `expected_regex`

```
htf.assertions.assert_regex(text: str, expected_regex: str, message: str | None = None) →
None
```

Assert that `text` matches regular expression `expected_regex`.

Parameters:

- **text** – a text to be matched
- **expected_regex** – a regular expression to be used
- **message** – the message to prepend to the error message

Raises:
AssertionError – if `text` does not match regular expression `expected_regex`

```
htf.assertions.assert_sequence_equal(a: Sequence, b: Sequence, message: str | None = None,
sequence_type: Type | None = None) → None
```

Assert that `a` equals `b` and that both are sequences.

Parameters:

- **a** – a sequence
- **b** – a sequence
- **message** – the message to prepend to the error message
- **sequence_type=None** – the sequence type to be used (if not `None`)

Raises:
AssertionError – if `a` and `b` are not equal or don't match the `sequence_type`

```
htf.assertions.assert_set_equal(a: Set, b: Set, message: str | None = None) → None
```

Assert that `a` equals `b` and that both are of type `set`.

Parameters:

- **a** – a set
- **b** – a set
- **message** – the message to prepend to the error message

Raises:
AssertionError – if `a` and `b` are not equal or not sets

```
htf.assertions.assert_str_equal(a: str, b: str, message: str | None = None) → None
```

Assert that `a` equals `b` and that both are of type `str`.

Parameters:

- **a** – a string
- **b** – a string
- **message** – the message to prepend to the error message

Raises:
AssertionError – if `a` and `b` are not equal or not strings

```
htf.assertions.assert_true(expression: bool, message: str | None = None) → None
```

Assert that `expression` is `True`.

Parameters:

- **expression** – the boolean expression to be validated
- **message** – the message to prepend to the error message

Raises:
AssertionError – if `expression` is not `True`

```
htf.assertions.assert_tuple_equal(a: Tuple, b: Tuple, message: str | None = None) → None
```

Assert that `a` equals `b` and that both are of type `tuple`.

Parameters:

- **a** – a list
- **b** – a list
- **message** – the message to prepend to the error message

Raises:

AssertionError – if `a` and `b` are not equal or not tuples

```
htf.assertions.get_equality_asserter(type_: Type) → Callable[[...], None]
```

Return the registered equality asserter for `type_`.

Parameters:
type – a type
Returns:
the registered equality asserter for `type`
Raises:
KeyError – if `type_` has no registered equality asserter

```
htf.assertions.set_diff_threshold(threshold: int) → None
```

Set the diff threshold to `threshold`:

Parameters:
threshold – the maximum number of characters to use difflib

```
htf.assertions.set_equality_asserter(type_: Type, asserter: Callable[[...], None]) → None
```

Register a new type equality asserter used in `assert_equal` and `assert_not_equal`.

Parameters:

- **type** – the type the checker is used for
- **asserter** – callable equality asserter object that supports parameters `a`, `b` and `message`

```
htf.assertions.set_repr_length(length: int) → None
```

Set the maximum representation length to `length`

Parameters:
length – the maximum representation length

For legacy tests the `htf.TestCase` offers wrappers for all built-in assertions and also non-pep8 wrappers to support legacy tests.

Behavior Driven Development

Behavior Driven Development (BDD) is an agile software development technique. BDD enables non-technical participants to participate in writing tests.

The HILSTER Testing Framework enables users to write features in a gherkin-like language with add-ons that can be run as tests with seamless integration into the existing ecosystem.

Tests are written in form of Features, Rules, Scenarios and Steps, which are either Given, When, or Then steps. It is also possible to create Data Driven Feature Tests.

Thus every step is implemented in Python based on HILSTER Testing Framework.

HILSTER Testing Framework also offers requirements coverage in combination with the Dashboard.

Features

A feature file describes a feature in natural language with scenarios describing actions and the expected outcome. The filename ends with `.feature` with `UTF-8 encoding`. Every feature file must contain one single feature. Every feature can contain one or multiple scenarios or scenario outlines.

A feature may contain further keywords to describe how tests may run.

Lines starting with `#` are comments.

Scenarios

Scenarios are “tests” which consist of `Given`, `When`, and `Then` statements. They describe preconditions, actions as well as the expected outcomes.

Steps

`Given` steps specify preconditions, which describe the state of the environment. They are used to put the tested system into an initial state.

`When` steps specify conditions, for example `when car turns right` is a condition. They are used to take actions.

`Then` steps specify assertions and serve for checking if conditions are met. They are used to observe outcomes.

Each statement can be repeated with `And` as well as `But`.

HILSTER Testing Framework finds the correct implementation of these steps so that they can be executed as a test.

Writing Features

A feature is written in a file named `<feature-name>.feature`.

The feature description is written with the `Feature:` keyword followed by a feature name and an optional indented documentation string in the next lines.

```
Feature: Example features without info string
```

```
Feature: Example features with info string
  This documentation string is optional.
```

Writing Scenarios

A scenario is described inside a `Scenario:` keyword. It is indented compared to the feature.

```
Feature: Heating
  Scenario: Heat up
    Given the refrigeration machine controller is running at 100 rpm
    And the environmental temperature is 21 °C
    When the initial temperature is -100 °C
    Then the refrigeration machine controller does not cool down
```

Example Feature

The following example contains a very simple feature with a single scenario.

```
Feature: This is an example feature
    This features is only used as an example

    Scenario: Example
        Given we write an example
        When the interested reader reads it
        Then he will understand how BDD works
```

Complex Scenarios

As an extension to BDD, scenarios support repeated keywords which allow you to create more complex scenarios.

```
Feature: This is an example feature
    This features is only used as an example

    Scenario: Complex Example
        Given we write an example
        When the interested reader reads it
        Then he will understand how BDD works

        Given we write another example
        When the interested reader reads it, too
        Then he will understand how BDD works for sure
```

Implementing Steps

Steps are implemented in Python as methods that are decorated with `htf.given`, `htf.when` and `htf.then` decorators.

The following code shows the implementation of the corresponding steps so that this feature can be run as a test.

```
@htf.given("we write an example")
def we_write_an_example():
    pass

@htf.when("the interested reader reads it")
def the_interested_reader_reads_it():
    pass

@htf.then("he will understand how BDD works")
def he_will_understand_how_bdd_works():
    pass
```

The corresponding steps are found via pattern matching. Details are described later.

Steps can be async, too.

```
@htf.given("we write an example")
async def we_write_an_example():
    pass

@htf.when("the interested reader reads it")
async def the_interested_reader_reads_it():
    pass

@htf.then("he will understand how BDD works")
async def he_will_understand_how_bdd_works():
    pass
```

```
htf.given(precondition: str, parser: str | None = None, extra_types: Dict[Any, Any] | None =
None, converters: Dict[str, Any] | None = None) → Callable[[Callable[[...], Any]], Any]
```

Decorates a method to make it an implementation of a given step in a behavior driven test. See also https://cucumber.io/docs/gherkin/reference/#given .

Parameters:

- **precondition** – gherkin feature precondition
- **parser=None** – the parser to parse the parameters from the precondition
- **extra_types=None** – extra types for parsing
- **converters=None** – optional converters that are applied to parameters after parsing

```
htf.when(condition: str, parser: str | None = None,
extra_types: Dict[Any, Any] | None = None, converters: Dict[str, Any] | None = None) →
Callable[[Callable[[...], Any]], Any]
```

Decorates a method to make it an implementation of a when step in a behavior driven test. See also https://cucumber.io/docs/gherkin/reference/#when .

Parameters:

- **condition** – gherkin feature condition
- **parser=None** – the parser to parse the parameters from the condition
- **extra_types=None** – extra types for parsing
- **converters=None** – optional converters that are applied to parameters after parsing

```
htf.then(assertion: str, parser: str | None = None,
extra_types: Dict[Any, Any] | None = None, converters: Dict[str, Any] | None = None) →
Callable[[Callable[[...], Any]], Any]
```

Decorates a method to make it an implementation of a then step in a behavior driven test. See also https://cucumber.io/docs/gherkin/reference/#then .

Parameters:

- **assertion** – gherkin feature assertion
- **parser=None** – the parser to parse the parameters from the assertion
- **extra_types=None** – extra types for conversion
- **converters=None** – optional converters that are applied to parameters after parsing

Running Features

Run `htf` by giving the specifier for `feature` file, and also the `<step-implementation>.py` file. Features and normal tests can also be mixed up.

In Python you can run:

```
htf.main(tests=["steps.py", "example.feature"])
```

And on the command-line you can run:

```
htf steps.py example.feature
```

Steps with Parameters

You can implement steps with parameters, too. This allows to use one step implementation for more than one step in a feature file.

```
Feature: Feature with parameters in steps

    Scenario: Monkey eats many Bananas
        Given the monkey is awake
        When the monkey eats 10 bananas
        Then he is not hungry anymore

    Scenario: Monkey eats two Bananas
        Given the monkey is awake
        When the monkey eats 2 bananas
        Then he is still hungry
```

The `When` step with the parameter to read the number of bananas is implemented in the following example.

```
@htf.when("the monkey eats {number_of_bananas} bananas")
def monkey_eats_bananas(number_of_bananas):
    print(f"Monkey eats {number_of_bananas} bananas")
```

This also works for the other steps.

There are also other parsers for more complex situations.

Long Lines

Long lines can be split up to multiple lines by adding a `\` at the end.

```
Feature: Feature with long lines

    Scenario: Monkey eats many Bananas
        Given the monkey is awake
        When the monkey eats \
             10 bananas
        Then he is not \
             hungry \
             anymore
```

Multi-Language Support

Features can be written in natural languages and do not need to use the English language. The first line of a feature file controls the language. The default language is English (`en`).

The following example uses German as the language.

```
# language: de
Funktion: Heizen
  Szenario: Aufheizen
    Angenommen die Maschine läuft mit 100 Umdrehungen pro Minute
```

```
    Wenn die initiale Temperatur 100 °C beträgt
    Dann erreicht die Temperatur der Maschine nicht 120 °C
```

Context Fixture

If you need to pass data between steps you can use the `htf.fixtures.context` fixture.

Other fixtures can be used like expected. Step parameters are supplied on the left side.

```
@htf.when("the monkey eats {number_of_bananas} bananas")
def monkey_eats_bananas(number_of_bananas, context):
    print(f"Monkey eats {number_of_bananas} bananas")
    context.number_of_bananas = int(number_of_bananas)

@htf.then("he is not hungry anymore")
def monkey_is_not_hungry_anymore(context, assertions):
    assertion.assert_greater(context.number_of_bananas, 5, "The monkey did not eat enough bananas!")

@htf.then("he is still hungry")
def monkey_is_still_hungry(context, assertions):
    assertion.assert_less_equal(context.number_of_bananas, 5,
                                "The monkey ate too much bananas! The monkey is dead now.")
```

To set the actual result of a step, the fixture `htf.fixtures.context` contains `current_step`, which is the `htf.fixtures.step` instance in the current context.

```
@htf.then("the current number of bananas is {number_of_bananas}")
def check_current_number_of_bananas(number_of_bananas, context):
    current_number_of_bananas = 10
    context.current_step.set_actual_result(current_number_of_bananas)
    htf.assert_almost_equal(current_number_of_bananas, number_of_bananas)
```

Attach Data to Steps

You can attach more complex data to steps compared to parameters by adding a data table or text in the feature. The data is passed via the `htf.fixtures.context` fixture as `table` or `text` attribute.

```
Feature: Feature with Data

    Scenario: Monkey feeding
        When the monkey eats bananas
            | i | name   |
            | 1 | first  |
            | 2 | second |
        And the monkey eats bananas and says
            """
            This text is said while eating bananas
            """
            | i | name   |
            | 3 | third  |
```

```
            | 4 | fourth |
        Then the monkey says
            """
            Baarrrb.
            """
```

The implementation of the steps looks like the following

```
@htf.when("the monkey eats bananas")
def monkey_eats_bananas(context):
    for item in context.table:
        print(f"Eat the {item['i']}th banana called {item['name']}")

@htf.when("the monkey eats bananas and says")
def monkey_eats_bananas(context):
    for item in context.table:
        print(f"Eat the {item['i']}th banana called {item['name']}")
        print(f"Monkey: {context.text}")

@htf.then("the monkey says")
def monkey_says(context):
    print(f"Monkey: {context.text}")
```

Tagging

HILSTER Testing Framework offers the possibility to add textual tags to features and scenarios as well as scenario outlines.

To do this use the `Tags:` keyword followed by a list of comma-separated strings.

```
Feature: Feature with Tags

    Tags: Tag-1, Tag-2, Tag-3

    Scenario: Scenario with Tags
        Tags: Tag-4, Tag-5, Tag-6
        # ...
```

Tags are combined and put into the test result and thus can be used to filter text by tags as mentioned in Tagging.

Requirements

HILSTER Testing Framework offers the possibility to add textual requirements to features and scenarios as well as scenario outlines.

To do this use the `Requirements:` keyword followed by a list of comma-separated strings.

```
Feature: Feature with Requirements

    Requirements: Req-1, Req-2, Req-3

    Scenario: Scenario with Requirements
        Requirements: Req-4, Req-5, Req-6
        # ...
```

The requirements are combined and put into the test result and thus can be used to perform requirements coverage in combination with the Dashboard.

Implemented Tests

HILSTER Testing Framework offers the possibility to add links to implemented tests to features and scenarios.

To do this use the `Implements:` keyword followed by a list of comma-separated strings. Each entry can be a url or a simple id.

```
Feature: Feature with implemented tests

    Implements: Test-1, https://host:port/path/to/Test-2

    Scenario: Scenario with implemented tests
        Implements: Test-3
        # ...
```

The implemented tests are added to the test report and used to send test results back to ALM/QMS systems.

Background Steps

The keyword `Background:` can be used when scenarios inside a feature have intersecting preconditions. It contains only `Given` preconditions that are automatically run in every scenario before running the other steps. It can be used to realize common preconditions.

```
Feature: Refrigeration machine can preserve internal heat correctly

    Background:
        Given the refrigeration machine controller is running at 100 rpm

    Scenario: Heat up
        Given the environmental temperature is 21 °C
        # ...

    Scenario: Cool down
        Given the environmental temperature is 21 °C
        # ...
```

Preconditions for `Background:` are implemented like normal given steps with `htf.given`.

Rules

The `Rule:` keyword is optionally used for grouping together related scenarios when they belong to the same feature.

```
Feature: Monkey movements are correct
  Rule: Monkeys can run if they are healthy
    Scenario: Baboon can run
        Given baboon is healthy and adult
        Then baboon can run
    Scenario: Chimp
        Given chimp is healthy and adult
        Then chimp can run

  Rule: Another rule
     # ...
```

Scenario Outlines

A scenario outline is a scenario template that dynamically generates scenarios. It is the behavior driven way to realize Data Driven Testing. It consists of steps like a normal scenario that has template variables in it and one data source called `Examples`. When the scenarios are generated the template variables are replaced automatically.

```
Feature: Feature with Scenario Outline
  Scenario Outline: Machine does not cool down
    Given the refrigeration machine controller is running at <rpm> rpm
    When the initial temperature is <temperature> °C
    Then the refrigeration machine controller does not cool down

    Examples:
       | rpm | temperature |
       |  78 |         -10 |
       |  80 |          21 |
       |  90 |          25 |
       | 100 |          38 |
```

Running the examples leads to multiple dynamically generated scenarios with parameters:

```
Scenario: Machine does not cool down [rpm=78, temperature=-10] (Feature: ...)
Scenario: Machine does not cool down [rpm=80, temperature=21] (Feature: ...)
Scenario: Machine does not cool down [rpm=90, temperature=25] (Feature: ...)
Scenario: Machine does not cool down [rpm=100, temperature=38] (Feature: ...)
```

The implementation can be done with normal steps with parameters for example.

```
htf.given("the refrigeration machine controller is running at <rpm> rpm")
def machine_running_at(rpm):
    # this is called once for every line in the data table (78, 80, 90 and 100)

htf.when("the initial temperature is {temperature} °C)
def initial_temperature(temperature):
    # this is called once for every line in the data table (-10, 21, 25 and 38)
```

Scenario Outline Data Sources

Scenario outlines support multiple different data sources which can be data-tables, external CSV-, JSON, YAML-files and also Python generators. Every data source can have an optional title.

Data-Tables Data Sources

Data-tables are textual tables supplied directly in the feature file. The first line is a header. All other lines are data lines. A data table is parsed into a list of dictionaries with the keys from the header line.

```
Feature: Feature with Data-Table
    Scenario Outline: Data-Table Scenario
        Given there is a data-table with <key> and <value>

    Examples: Data-Table
        |  key | value |
        |  foo |   bar |
        | ding |  dong |
```

Running the examples leads to multiple dynamically generated scenarios with parameters:

```
Scenario: Data-Table Scenario [key=foo, value=bar] (Feature: ...)
Scenario: Data-Table Scenario [key=ding, value=dong] (Feature: ...)
```

CSV Data Sources

Instead of using data-tables you can also supply external data via a CSV file.

To do this you can supply an example with the `CSV:` keyword followed by a CSV filename. The filename can be an absolute path or a relative path. Relative paths are relative to the feature file where they appear.

The following example show the contents of `data.csv`

```
key,value
foo,bar
ding,dong
```

The following feature shows how to use CSV data.

```
Feature: External CSV Data
    Scenario Outline: CSV Scenario Outline
        Given there is a csv-data-file with <key> and <value>

    Examples: CSV Data-Source
        CSV: data.csv
```

Running the examples leads to multiple dynamically generated scenarios with parameters:

```
Scenario: CSV Scenario Outline [key=foo, value=bar] (Feature: ...)
Scenario: CSV Scenario Outline [key=ding, value=dong] (Feature: ...)
```

JSON Data Sources

JSON data sources are also supported via the `JSON:` keyword followed by a JSON filename.

The filename can be an absolute path or a relative path. Relative paths are relative to the feature file where they appear.

The following example show the contents of `data.json`

```
[
    {"key": "foo", "value": "bar"},
    {"key": "ding", "value": "dong"}
]
```

The contents have to be a list of dictionaries.

The following feature shows how to use CSV data.

```
Feature: External JSON Data
    Scenario Outline: JSON Scenario Outline
        Given there is a json-data-file with <key> and <value>

    Examples: JSON Data-Source
        JSON: data.json
```

Running the examples leads to multiple dynamically generated scenarios with parameters:

```
Scenario: JSON Scenario Outline [key=foo, value=bar] (Feature: ...)
Scenario: JSON Scenario Outline [key=ding, value=dong] (Feature: ...)
```

YAML Data Sources

YAML data sources are also supported via the `YAML:` keyword followed by a YAML filename.

The filename can be an absolute path or a relative path. Relative paths are relative to the feature file where they appear.

The following example show the contents of `data.yml`

```
- key: foo
  value: bar
- key: ding
  value: dong
```

The contents have to be a list of dictionaries.

The following feature shows how to use CSV data.

```
Feature: External YAML Data
    Scenario Outline: YAML Scenario Outline
        Given there is a yaml-data-file with <key> and <value>

    Examples: YAML Data-Source
        YAML: data.yml
```

Running the examples leads to multiple dynamically generated scenarios with parameters:

```
Scenario: YAML Scenario Outline [key=foo, value=bar] (Feature: ...)
Scenario: YAML Scenario Outline [key=ding, value=dong] (Feature: ...)
```

Python Generators Data Sources

Python generators can also be used as data sources via the `Generator:` keyword followed by a generator title.

Every data generator needs to be decorated with `htf.data_generator`. The following Python code can be used as data sources.

```
@htf.data_generator("Python-based Generator")
def data_generator() -> Generator[Dict[str, str], None, None]:
    yield dict(key="foo", value="bar")  # this is the most efficient way
    yield dict(key="ding", value="dong")
    # ...

@htf.data_generator("Python-based Data Source with Lists")
def data_source_with_list() -> List[Dict[str, str]]:
    return [  # this also works
        dict(key="foo", value="bar"),
```

```
        dict(key="ding", value="dong")
        # ...
    ]
```

Async Python generators are supported, too.

```
@htf.data_generator("Python-based Generator")
async def data_generator() -> AsyncGenerator[Dict[str, str], None]:
    yield dict(key="foo", value="bar")  # this is the most efficient way
    yield dict(key="ding", value="dong")
    # ...
```

The data generator must return an iterable so you can make it a Python generator or let it return an iterable object like a list for example.

The following feature shows how to use a Python generator as a data source.

```
Feature: Python Generator Data Source
    Scenario Outline: Data Source Scenario Outline
        Given there is a data-source yielding <key> and <value>

    Examples: Python Generator Data-Source
        Generator: Python-based Generator
```

Running the examples leads to multiple dynamically generated scenarios with parameters:

```
Scenario: Data Source Scenario Outline [key=foo, value=bar] (Feature: ...)
Scenario: Data Source Scenario Outline [key=ding, value=dong] (Feature: ...)
```

```
htf.data_generator(pattern: str, parser: str | None = None) → Callable[[Callable[[...],
Any]], Any]
```

Decorates a method to make it an implementation of a data generator used for examples in a behavior driven test.

Parameters:

- **pattern** – the pattern to match the title
- **parser=None** – the parser to match the name of the example

Multiple and Combined Data Sources

Every scenario outline can have multiple data sources that can also be mixed.

```
Feature: Mixed External Data
    Scenario Outline: Scenario Outline with Mixed Data
```

```
        Given there is a data-table with <key> and <value>

    Examples:
        |  key | value |
        |  foo |   bar |
        # CSV: data.csv
        # JSON: data.json
        # YAML: data.yml
        # Generator: Python-based Generator
        # etc.
```

Transforming Data Sources

Sometimes you need to precalculate values based on data-sources. To do this HILSTER Testing Framework supports data-transformation.

A data transformation is created by decorating a method with the `htf.transformation` decorator. The method is called for every line of the data source. To use a data-transformation the data source (`Example:`) need to have a name supplied.

In the following example the Addition functionality for a calculator is tested. The data-source only contains to addends but not the required result. To check if the calculator is working properly the result needs to be precalculated.

```
Feature: Addition

  Scenario Outline: Addition
    Given the calculator is cleared
    When <a> is added to <b>
    And the equals button is pressed
    Then the result is <result>

    Examples: Addition
      |   a |   b |
      |   1 |   1 |
      |   2 |  12 |
```

To implement a data-transformation hook you could use the following code:

```
@htf.transformation("Addition")
def expected_addition_result(data):
    data["result"] = int(data["a"]) + int(data["b"])
    return data
```

Running the examples leads to multiple dynamically generated scenarios with parameters where `result` is generated on the fly.

Transformations can be async, too.

```
@htf.transformation("Addition")
async def expected_addition_result(data):
    data["result"] = int(data["a"]) + int(data["b"])
    return data
```

```
Scenario: Addition [a=1, b=2, result=3] (Feature: ...)
Scenario: Addition [a=2, b=12, result=14] (Feature: ...)
```

```
htf.transformation(pattern: str, parser: str | None = None) → Callable[[Callable[[...],
Any]], Any]
```

Decorates a method to make it an implementation of a data transformation hook used for examples in a behavior driven test.

Parameters:

- **pattern** – gherkin examples pattern
- **parser=None** – the parser to match the name of the example

Skipping Features, Scenarios or Scenario Outlines

You can skip features, scenarios or scenario outlines by adding a line `Skip: <reason>` to your feature.

To skip a whole feature you can use:

```
Feature: Skipped Feature
    Skip: this feature is skipped
    Scenario: Skipped Feature Scenario
        Given there is a skipped feature
```

To skip a scenario you can use:

```
Feature: Skipped Feature
    Scenario: Skipped Feature Scenario
        Skip: this scenario is skipped
        Given there is a skipped feature
```

To skip a scenario outline you can use:

```
Feature: Skipped Feature
    Scenario Outline: Skipped Feature Scenario Outline
        Skip: this scenario is skipped
        Given there is a skipped feature

        Examples:
```

```
        |  key | value |
        |  foo |   bar |
```

Setup and Tear Down Code

It is possible to create setup and tear down code for features and scenarios, too.

To do this you can use `htf.feature` and `htf.scenario`.

The decorated methods can be returning methods to only implement setup code or can be implemented as generators yielding one element to implement setup and tear down code.

Fixtures and parameters are added like for the other step implementations.

```
Feature: Feature with Setup and Tear Down code

    Scenario: Setup and Tear Down
        Given the setup was run
        when actions are performed
        then an outcome will be available
```

In the following example only setup code for a feature and a scenario is implemented.

```
@htf.feature("Feature with Setup and Tear Down code")
def feature_set_up(context):
    # your feature setup code comes here

@htf.scenario("Setup and Tear Down")
def scenario_set_up(context):
    # your scenario setup code comes here
```

And in the following example setup and tear down code is implemented.

```
@htf.feature("Feature with Setup and Tear Down code")
def feature_set_up_and_tear_down(context):
    # your feature setup code comes here
    yield  # now the scenario is run
    # your feature tear down code comes here

@htf.scenario("Setup and Tear Down")
def scenario_set_up(context):
    # your scenario setup code comes here
    yield  # now the scenario is run
    # your scenario tear down code comes here
```

Setup and tear down code can be async, too.

```
htf.feature(pattern: str, parser: str | None = None, extra_types: Dict[Any, Any] | None =
None, converters: Dict[str, Any] | None = None) → Callable[[Callable[[...], Any]], Any]
```

Decorates a method to make it an implementation of a given feature in a behavior driven test.

It can be implemented as a normal method with a return value to implement set up code or as a generator to realize set up and tear down code for a feature.

Parameters:

- **pattern** – gherkin feature pattern
- **parser=None** – the parser to parse the parameters from the precondition
- **extra_types=None** – extra types for parsing
- **converters=None** – optional converters that are applied to parameter after parsing

```
htf.scenario(pattern: str, parser: str | None = None, extra_types: Dict[Any, Any] | None =
None, converters: Dict[str, Any] | None = None) → Callable[[Callable[[...], Any]], Any]
```

Decorates a method to make it an implementation of a given scenario in a behavior driven test.

It can be implemented as a normal method with a return value to implement set up code or as a generator to realize set up and tear down code for a scenario.

Parameters:

- **pattern** – gherkin feature pattern
- **parser=None** – the parser to parse the parameters from the precondition
- **extra_types=None** – extra types for parsing
- **converters=None** – optional converters that are applied to parameters after parsing

Parsing Steps

HILSTER Testing Framework offers three different parsers to parse steps and to find the implementation for a step by its name.

The default parser is based on the `parse` module. There is an extended version of `parse` called `cfparse`. And there is also a regular-expression parser (`re`).

All parsers support pattern matching and type casting.

How Parsing and Matching Works

HILSTER Testing Framework collects all implemented steps and features. When features, scenarios and steps are run the implementing step is looked up by iterating over all collected steps with the corresponding scope and matching the current step to the pattern using a parser.

If there is one match the step will be executed with optional parameters extracted. Parameters can also be converted to other types before calling the implementing method.

Using the Default Parser (parse)

The default step parser is based on the `parse` packet that is the opposite of Python's `format` method. It supports the Format String Syntax.

Parameters are put between `{` and `}` (e.g. `{number}`) and can have type casts in the format expression in the form of `{[parameter name]:[format specification]}`.

The parsed parameters are passed to the implementing method by its name.

The following Gherkin example describes addition.

```
Feature: Addition

  Scenario: Addition
    Given the calculator is cleared
    When 1 is added to 2
    And the equals button is pressed
    Then the result is <result>
```

The following example parses `a` and `b` that are added as strings that are added.

```
@htf.when("{a} is added to {b}")
def add(a, b, context):
    context.expected_result = int(a) + int(b)  # this type-cast has to be performed here!
```

In the example the parameters `a` and `b` are passed as strings so they need to be converted to `int` in the implementation.

To automatically convert `a` and `b` to int while parsing you can change the format string to:

```
@htf.when("{a:g} is added to {b:g}")
def add(a, b, context):
    context.expected_result = a + b  # a and b are int
```

You can find more information about the type conversion on GitHub parse repository.

Using the Regular-Expression-Parser (re, regex)

The `re` parser uses regular-expressions to do the parsing. Thus it is the most flexible parser but is more complex.

To enable the CF-Parser the `parser` argument of the step-decorator has to be set with `cf` or `cfparse` and `converters` can to be supplied optionally.

`converters` is a dictionary of callables where the keys are the names of the parameters of the implementing method.

The regular-expression must make use of named subgroups (e.g. `r"(?P<parameter name>\w+)"`). You can find more information about named subgroups in the Python re Module.

```
Feature: Addition

  Scenario: Addition
    Given the calculator is cleared
    When 1 is added to 2
    And the equals button is pressed
    Then the result is <result>
```

The following example parses `a` and `b` that are added as strings that are added.

```
@htf.when(r"(?P<a>\d+) is added to (?P<b>\d+)", parser="re")
def add(a, b, context):
    context.expected_result = int(a) + int(b)  # this type-cast has to be performed here!
```

In the example the parameters `a` and `b` are passed as strings so they need to be converted to `int` in the implementation.

To automatically convert `a` and `b` to int while parsing you can change the format string to:

```
@htf.when(r"(?P<a>\d+) is added to (?P<b>\d+)", parser="re", converters=dict(a=int, b=int))
def add(a, b, context):
    context.expected_result = a + b  # a and b are int
```

Using the CF-Parser (cfparse, cf)

The CF-Parser extends the default with support for cardinality fields, and it automatically creates type variants to parse repeated parameters.

To enable the CF-Parser the `parser` argument of the step-decorator has to be set with `cf` or `cfparse` and `extra_types` have to be supplied, too.

The following examples show how to accumulate a list of integers with a variable length.

The following example accumulates a list of numbers with variable amount.

```
Feature: Accumulation
  Scenario: Accumulate 1
    When 1 is accumulated
    Then the result is 1

  Scenario: Accumulate 2
    When 1, 2 is accumulated
    Then the result is 3

  Scenario: Accumulate many
```

```
    When 1, 2, 3, 4, 5, 6, 7, 8, 9 is accumulated
    Then the result is 45
```

The Python-implementation looks like

```
import parse

@parse.with_pattern(r"\d+")
def parse_number(text):
     return int(text)

extra_types = dict(Number=parse_number)

@htf.when("{numbers:Number+} is accumulated", parser="cf", extra_types=extra_types)
def accumulate(numbers, context):
    context.accumulated_numbers = sum(numbers)

@htf.then("the result is {result:g}")
def the_result_is(result, context):
    htf.assert_equal(result, context.accumulated_numbers)
```

You can find more information about cardinality field support on GitHub parse-type repository.

Getting Available Steps and Statements

As a developer you need to get all available steps and statements without looking into the code all the time.

This can be done using `htf.get_statements` and `htf statements <steps/test specifiers>`.

On the command-line you can run:

```
htf statements steps.py

Collecting statements

Given statements:
Given the refrigeration machine controller is running at {speed:g} rpm

When conditions:
When the initial temperature is {temparature:g} °C
When {numbers:Number+} is accumulated

Then assertions:
Then the result is {result:g}
Then the refrigeration machine controller is cooling down
Then the refrigeration machine controller does not cool down

Features:
.*

Scenarios:
.*
```

```
Transformations:
X and Y data

Data Generators:
Data Generator
```

And from Python you can use `htf.get_statements`:

```
htf.get_statements("steps.py")
>>> {
    'given': [
        'Given the refrigeration machine controller is running at {speed:g} rpm'
    ],
    'when': [
        'When the initial temperature is {temparature:g} °C',
        'When {numbers:Number+} is accumulated'
    ],
    'then': [
        'Then the refrigeration machine controller is cooling down',
        'Then the refrigeration machine controller does not cool down',
        'Then the result is {result:g}'
    ],
    'features': ['.*'],
    'scenarios': ['.*'],
    'transformations': ['X and Y data'],
    'data_generators': ['Data Generator']
}
```

```
htf.get_statements(tests: Any | List[Any] = '__main__') → Dict[str, List[str]]
```

Get a dict of behavior driven development statements found in the specified tests.

Parameters:
tests=None – a test-specifier or a list of test-specifiers (folder, file, test-case, test-case-method, module)
Returns:
a dict with all behavior driven development statements found
Return type:
dict

Examples

You can find examples in the htf-demo, too.

htf — Command line utility

The HILSTER Testing Framework comes with a command line utility called `htf`.

`htf` can be used to run tests, open docs and view the included open-source licenses.

Running tests

To run all tests within the current folder simply run

```
htf
```

By default `htf` creates an HTML-testreport called `testreport.html` in the current folder.

Specifying tests

`htf` may be followed by `run` and `<tests>`. You can also omit `run` and only supply test-specifiers, eg.

```
htf run <tests>
```

respectively

```
htf <tests>
```

`<tests>` is a list of test-specifiers. They are separated by whitespaces.

A test-specifier may be a python module or a feature file, a globbing-expression for python modules (e.g. `test_*.py`), a globbing expression for feature files (e.g. `features/*.feature`), a folder or an import string. Test-specifiers can be mixed.

If a test-specifier is a python module the file is imported and all testable objects are collected into a test suite that is used for the test run.

```
htf test_1.py
```

If a test-specifier ist a globbing-expression the expression is evaluated and all matching files are imported.

```
htf test_\*.py
```

Note: the `\*` lets not `Bash` (or any other shell) evaluate it and passes it to `htf`.

If a test-specifier is a folder the folder is searched recursively and all python modules found within (see File pattern) are imported and all testable objects are collected into a test suite. Subsequently the test suite is executed.

Consider the folder `tests`, which contains python modules with unit tests. To execute all test cases in the folder `tests`, simply run

```
htf tests
```

In case `tests` is an importable package or module, located in the python search path, the names might collide. In this case, simply use

```
htf tests/
```

If a test-specifier is an import string, this may be a package, a module, a class (inheriting from `htf.TestCase`) or a method.

If a test-specifier is a package or a module, it is imported and containing tests are executed.

```
htf tests  # Example for a python package containing tests
htf tests.test_example  # Example for a python module containing tests
```

If a class is used it should be a testcase inheriting from `htf.TestCase`. This testcase is used in a test suite and all tests are run.

```
htf tests.test_example.ExampleTestCase # Example for a class containing tests
```

If a method is used it should be a method within a test case.

```
htf tests.test_example.ExampleTestCase.test_one # Example for a test method
```

Running multiple tests

To run multiple tests within a test run simply add more test-specifiers at the end.

```
htf test1 test2 test3
```

Different test-specifiers can also be mixed

```
htf tests/ test1.Test1TestCase test2.py
```

Test-title

To specify the test's title add the `-T` or `--title` option followed by a string that will be used as the title. If the title contains whitespaces, make sure to put quotes around it.

```
htf --title="This is my first test" tests/
```

HTML-report

By default `htf` generates an HTML-report called `testreport.html`. To specify an HTML-report add `-H` or `--html-report`.

```
htf --html-report="tests.html" tests/
```

This option may be repeated to generate multiple HTML-reports.

```
htf --html-report="tests1.html" --html-report="tests2.html" tests/
```

To open all HTML-reports use `-o` or `--open-report`.

```
htf --html-report="tests.html" -o tests/
```

JUnit-XML-report

`htf` is also able to generate JUnit-XML-compatible XML-reports. The reports can be evaluated by different tools, eg. Jenkins.

To specify an XML-report add `-x` or `--junit-xml-report`.

```
htf --junit-xml-report=results.xml tests/
```

This option may also be repeated.

JSON-report

`htf` is also able to generate JSON-reports.

To specify a JSON-report add `-j` or `--json-report`.

```
htf --json-report=results.json tests/
```

This option may also be repeated.

YAML-report

`htf` is also able to generate YAML-reports.

To specify a YAML-report add `-Y` or `--yaml-report`.

```
htf --yaml-report=results.yaml tests/
```

This option may also be repeated.

Report Server

To send test results to a test report server (hre) use `-r` or `--report-server`.

```
htf -r https://reports.host/project/token
htf --report-server=https://reports.host/project/token
```

To disable SSL-verfification you can set the environment variable `HTF_INSECURE` to any value.

```
HTF_INSECURE=1 htf -r https://reports.host/project/token  # Linux
set HTF_INSECURE=1  # Windows
htf -r https://reports.host/project/token  # Windows
```

Draft Reports

To create draft reports after each test use `-1` or `--create-drafts`.

```
htf -1
```

or

```
htf --create-drafts
```

Minimized Report Size

To minimize the report size use the `-M` or `--minimize-report-size` switch. When used for example captured stdout and stderr is only kept for failed tests. By default the report size is not minimized.

```
htf -M tests/
```

Shuffle Tests

To shuffle tests before running add `-S` or ``--shuffle`.

```
htf --shuffle tests/
```

To set the shuffle seed use `--shuffle-seed=<int>|last`. If `'last'` is used the seed is loaded from `'shuffle_seed.txt'`. If the file cannot be found one seed is created.

After a seed is created it is stored to be used next time. Using the seed the shuffle result can be reproduced.

```
htf --shuffle --shuffle-seed=12345 tests/
htf --shuffle --shuffle-seed=last tests/
```

Filename-templates

Filenames for reports can include prepopulated templates.

Available templates:

- `{{title}}` - the title as a filename
- `{{date}}` - the current date `"%Y-%m-%d_%H-%M-%S"`
- `{{hostname}}`, `{{host}}` or `{{node}}` - the hostname
- `{{htf_version}}` or `{{version}}` - the htf version, eg. `htf_1.0.0`
- `{{python_version}}` - the python version, eg. `Python_3.6.1`

To generate an HTML-report containing the current node and the current date use

```
htf -H test_{{host}}_{{date}}.html tests/
```

Fail fast

If `-f` or `--fail-fast` is used the test run ends after the first failing test.

File pattern

If a test-specifier is a folder the default pattern used for file discovery is `test*.py`. The pattern can be changed using the `-p` or `--pattern` options.

```
htf -p \*.py tests/
```

Wildcards (*) are supported. Depending on your shell, escaping must be applied.

Tagging

To select tests using a logical expression use the `-t` or `--tags` option followed by an expression.

```
htf --tags='foo|bar'
```

To list all available tags use the `tags` commands.

```
htf tags /path/to/test
```

To use tags for fixtures use `-F``or ``--fixture-tags` in addition.

```
htf -F hardware
htf --fixture-tags=hardware
```

Metadata

To add metadata about the test run use the `-m` or `--metadata` option followed by a comma-separated list of key-value pairs.

These options can also be repeated.

This feature can for example be used to add information about a tested firmware version, etc.

```
htf -m key1=value1,key2=value2 --metadata key3=value3  # etc.
```

The metadata will occur in the test reports.

Overwriting Settings

You can overwrite settings and even hierarchical settings from command line using `-s <name>=<value>` or `--setting <name>=<value>`.

Hierarchies in settings can be realized with a `.` e.g. `-s top.center.bottom=1`.

For example the following call

```
htf -s a=1,b=2 -s top.sub=3
```

leads to settings looking like

```
{
    'a': '1',
    'b': '2',
    'top': {
        'sub': '3'
    }
}
```

Please note that all supplied settings are strings and you have to care about the casting when these will be used.

This option support to do manual experiments, etc.

Parameters

You can add parameters to test runs from command line to control the behavior of tests and fixtures. Add `-P <name>=<value>` or `--parameter <name>=<value>` to the call.

The parameters are available via the `htf.fixtures.Parameters` fixture.

```
htf -P name1=value1,name2=value2 --parameter=name3=value3
```

The parameters will also appear in the test result metadata.

Bash-completion

`htf` supports bash-completion which provides automatic command completion for the `bash` shell.

Bash-completion completes the first positional commands (`run`, `docs` and `licenses`, etc.) but also expands test-specifiers (eg. file names, packages, modules, classes and methods) and other parameters like `--html-report`, `--metadata`, etc.

Using the bash-completion makes it easy to specify tests (without typing-errors).

Let's assume you a have an importable python package called `tests`. Two test-modules called `test_1.py` and `test_2.py` are located within `tests`.

Both contain a test-case called `TestCase1` and `TestCase2`, respectively.

To easily run `tests.test_1.TestCase1`, type

```
htf te<TAB>
    tests    tests.
```

```
htf tests.<TAB>
htf tests.test_<TAB>
    tests.test_1    tests.test_1.    tests.test_2    tests.test_2.
htf tests.test_1.<TAB>
htf tests.test_1.TestCa<TAB>
htf tests.test_1.TestCase<TAB>
    tests.test_1.TestCase    tests.test_1.TestCase.
htf tests.test_1.TestCase<ENTER>
# ...
```

Enable Bash-completion

To enable bash-completion type

```
eval $(htf complete)
```

To persistently enable bash completion, add the command to your `~.bashrc`. alternatively put it into a new file called `/etc/bash_completion.d/htf`, eg.

```
echo "eval $(htf complete)" >> ~/.bashrc
. ~/.bashrc
```

or

```
echo "eval $(htf complete)" > /etc/bash_completion.d/htf
. /etc/bash_completion.d/htf
```

To check if bash-completion is enabled type

```
complete -p | grep htf
```

Open docs

To open the current docs in your webbrowser, type

```
htf docs
```

View licenses

To view the included and used open-source licenses, type

```
htf licenses
```

or

```
htf licenses --compact
```

to print the compact form.

To output the contents in Markdown format, type

```
htf licenses --markdown
```

or

```
htf licenses --markdown --compact
```

to print the compact form.

Show version

To show the `htf` version, type

```
htf version
```

htf.main() — Testscript utility

`htf.main` is used to start tests if not using `htf` (the command-line-utility) within a test-script.

```
htf.main(title: str = 'Testreport', tests: Any | List[Any] = '__main__', tags: str | None =
None, fixture_tags: str | None = None, html_report: str | List[str] | None = None,
junit_xml_report: str | List[str] | None = None, json_report: str | List[str] | None = None,
yaml_report: str | List[str] | None = None, report_server: str | List[str] | None = None,
extra_report: Any | List[Any] | None = None, create_drafts: bool = False, open_report: bool =
False, pattern: str = 'test*.py', metadata: Dict[str, Any] | None = None, parameters:
Dict[str, str] | None = None, exit: bool = True, fail_fast: bool = False,
minimize_report_size: bool = False, interactive: bool = False, interactive_address: str =
'0.0.0.0', interactive_port: int = 8080, open_browser: bool = True, shuffle: bool = False,
shuffle_seed: str | int | None = None) → int
```

Test runner.

Parameters:

- **title** – the test's title
- **tests=None** – a test-specifier or a list of test-specifiers (folder, file, test-case, test-case-method, module)
- **tags=None** – test filter expression
- **fixture_tags=None** – fixture filter expression
- **html_report=None** – HTML-report filename(s)
- **junit_xml_report=None** – JUnit-XML-report filename(s)
- **json_report=None** – JSON-report filename(s)
- **yaml_report=None** – YAML-report filename(s)
- **report_server=None** – Url or list of urls to report server
- **extra_report=None** – Extra reports that support instance.render(data). This is useful for `htf.DOORSTestReport` for example that needs additional parameters.
- **create_drafts=False** – if set to `True` draft reports are created after each test
- **open_report=False** – if set to `True` the HTML test report is opened after the test run
- **pattern="test*.py"** – the pattern to be used when searching for python files in folders
- **metadata=None** – a dictionary that contains metadata about the test run
- **parameters=None** – a dictionary that contains parameters for the test run
- **exit=True** – if set to `True` the exit() is called at the end of the tests
- **fail_fast=False** – if set to `True` the test run ends after the first failing test
- **minimize_report_size=False** – if set to `True` the report size is minimized.
- **interactive=False** – if set to `True` the tests are run interactively
- **interactive_address="0.0.0.0"** – the ip address the interaction server listens on.
- **interactive_port=8080** – the port the interaction server listens on.
- **open_browser=True** – if set to `False` browser is not opened automatically
- **shuffle=False** – set to `True` to shuffle tests
- **shuffle_seed=None** – the shuffle seed or 'last' to use the last shuffle seed

Returns:
`0` if the run was successful or the number of failed tests in case or errors and failures.
Return type:
int

Running tests

This section show some usage examples.

The first example covers the basic usage for a simple test-case running on Python 3.9+.

```
import htf

class ExampleTestCase(htf.TestCase):
    def test_example(self):
        self.assertTrue(True)
```

```
if __name__ == "__main__":
    htf.main()
```

This runs all tests within `ExampleTestCase` and generates an HTML-report names `testreport.html`.

Specifying tests

`htf.main` supports the `tests` parameter. It may be `None`, a test-specifier or a list of test-specifiers.

A test-specifier may be a python module, a feature file, a globbing-expression for python modules (e.g. `test_*.py`), a globbing expression for feature files (e.g. `features/*.feature`), a folder or an import-string (python style). In comparison to the `htf` command-line-utility it may also be a module-instance, a test-case or a test-case-method.

Test-specifiers can be mixed.

```
htf.main(tests=["<test-specifier1>", "<test-specifier2>", .. "<test-specifierN>"])
```

If only one test-specifier is supplied, it is not necessary to use a list

```
htf.main(tests="<test-specifier>")
```

If a test-specifier is a python module it is imported and all testable objects are collected into a test-suite that is used for the test run.

```
htf.main(tests="test_1.py")
```

If a test-specifier ist a globbing-expression the expression is evaluated and all matching files are imported.

```
htf.main(tests="test_*.py")
```

If a test-specifier is a folder this folder is searched recursively and all python modules found within (see File pattern, `pattern=`) are imported and all testable objects are collected into a test suite that is used for the test run.

Consider the folder `tests`, which contains python modules with unit tests. To execute all test cases in the folder `tests`, simply use

```
htf.main(tests="tests")
```

In case `tests` is an importable package or module, located in the python search path, the names might collide. In this case, simply use

```
htf.main(tests="tests/")
```

If a test-specifier is an import string, this may be a package, a module, a class (inheriting from `htf.TestCase`) or a method.

If a test-specifier is a package or a module, it is imported and containing tests are executed.

```
htf.main(tests=["tests", "tests.test_example"])
```

If a class is used it should be a testcase inheriting from `htf.TestCase`. This testcase is used in a test suite and all tests are run.

```
htf.main(tests=tests.test_example.ExampleTestCase)
```

If a method is used it should be a method within a test case.

```
htf.main(tests="tests.test_example.ExampleTestCase.test_one")
```

The examples above are analog to the command-line-utility `htf`.

In contrast to the command-line-utility htf, `htf.main` supports even more test-specifiers.

To test a module-instance use

```
import htf
import htf_examples.htf_main_1

if __name__ == "__main__":
    htf.main(tests=htf_examples.htf_main_1)
```

To test a test-case use

```
import htf

class ExampleTestCase(htf.TestCase):
    def test_example(self):
        self.assertTrue(True)
```

```
if __name__ == "__main__":
    htf.main(tests=ExampleTestCase)
```

And to test a test-case-method use

```
import htf

class ExampleTestCase(htf.TestCase):
    def test_example1(self):
        self.assertTrue(True)

    def test_example2(self):
        self.assertTrue(True)

if __name__ == "__main__":
    htf.main(tests=ExampleTestCase.test_example1)
```

Warning

When specifying methods as test specifiers in Python 3 the test class will be the class implementing the method and not necessarily the one specified. This means the methods called will also be the ones of the implementing class and may not be the ones you expect.

To clarify see the following example.

```
class Super:
    def whoami(self):
        print("Super")

    def test_whoami(self):
        self.whoami()

class Sub(Super):
    def whoami(self):
        print("Sub")
```

When running htf with `Sub.test_whoami` as a test specifier `Super.test_whoami` is executed instead. This is due to a limitation in Python 3 where the inheriting class can not be resolved from the function reference.

```
htf.main(tests=Sub.test_whoami)
```

To work around this issue you can either use the class itself as a specifier `Sub`, or pass an instance instead:

```
htf.main(tests=Sub().test_whoami)
```

Test-title

To specify the test-title use the `title=` argument.

```
htf.main(title="This is my first test")
```

HTML-report

By default `htf.main` generates an HTML-report called `testreport.html`. To specify an HTML-report use the `html_report=` argument.

```
htf.main(html_report="tests.html")
```

Multiple reports can be generated by supplying a list of filenames

```
htf.main(html_report=["tests1.html", "tests2.html"])
```

To open all HTML-reports use `open_report=True`.

```
htf.main(html_report="tests.html", open_report=True)
```

JUnit-XML-report

`htf.main` is also able to generate JUnit-XML-compatible XML-reports. The reports can be evaluated by different tools, eg. Jenkins.

To specify an XML-report use the `junit_xml_report=` argument.

```
htf.main(junit_xml_report="tests.xml")
```

or with multiple reports

```
htf.main(junit_xml_report=["tests1.xml", "tests2.xml"])
```

JSON-report

`htf.main` can also generate JSON-reports.

To specify a JSON-report use the `json_report=` argument.

```
htf.main(json_report="tests.json")
```

or with multiple reports

```
htf.main(json_report=["tests1.json", "tests2.json"])
```

YAML-report

`htf.main` can also generate YAML-reports.

To specify a YAML-report use the `yaml_report=` argument.

```
htf.main(yaml_report="tests.yaml")
```

or with multiple reports

```
htf.main(yaml_report=["tests1.yaml", "tests2.yaml"])
```

Other reports

There are other reports that need more parameters so that they need to be instantiated outside of `htf.main`.

For example `htf.DOORSTestReport` needs more information about report-module, requirements-modules and links-modules.

To use such a report use the `extra_report=` argument

```
import htf

class Tests(htf.TestCase):

    def test_assertionError(self):
        o = None
        print(o.no_there)

if __name__ == "__main__":
    doors_report = htf.DOORSTestReport(
                        filename="doors.dxl",
                        reportModule="/path/to/report/module",
                        requirementsModules={
                            "REQ_.*": "/path/to/requirements_module",
                            "TEST_.*": "/path/to/test_specification",
                        },
                        linksModules={
                            "REQ_.*": "/path/to/links/to/requirements_module",
                            "TEST_.*": "/path/to/links/to/test_specification",
                            }
                        )
    htf.main(extra_report=doors_report)
```

You can also supply a list of report instances

```
htf.main(extra_report=[report1, report2, ..., reportN])
```

Report Server

To send test results to a test report server (hre) use `report_server`.

```
htf.main(report_server="https://reports.host/project/token")
```

To disable SSL-verfification you can set the environment variable `HTF_INSECURE` to any value.

Draft Reports

To create draft reports after each test set `create_drafts=True`.

```
htf.main(create_drafts=True)
```

Minimized Report Size

To minimize the report size use `minimize=True`. When used for example captured stdout and stderr is only kept for failed tests. By default the report size is not minimized.

```
htf.main(minimize=True)
```

Shuffle Tests

To shuffle tests before running use `shuffle=True`.

```
htf.main(shuffle=True)
```

To set the shuffle seed use `shuffle_seed=<int>|'last'`. If `'last'` is used the seed is loaded from `'shuffle_seed.txt'`. If the file cannot be found one seed is created.

After a seed is created it is stored to be used next time. Using the seed the shuffle result can be reproduced.

```
htf.main(shuffle=True, shuffle_seed=12345)
htf.main(shuffle=True, shuffle_seed='last')
```

Filename-templates

Filenames for reports can include prepopulated templates.

Available templates:

- `{{title}}` - the title as a filename
- `{{date}}` - the current date `"%Y-%m-%d_%H-%M-%S"`
- `{{hostname}}`, `{{host}}` or `{{node}}` - the hostname
- `{{htf_version}}` or `{{version}}` - the htf version, eg. `htf_1.0.0`
- `{{python_version}}` - the python version, eg. `Python_3.6.1`

To generate an HTML-report containing the current node and the current date

```
htf.main(html_report="test_{{host}}_{{date}}.html")
```

Fail fast

If the `fail_fast=True` argument is used the test run ends after the first failing test.

File pattern

If a test-specifier is a folder the default pattern used for file discovery is `test*.py`. The pattern can be changed using the `pattern=` argument.

```
htf.main(tests="tests/", pattern="*.py")
```

Tagging

To select tests using a logical expression use the `tags` option set to an expression.

```
htf.main(tags="foo|bar")
```

To list all available tags use the `htf.get_tags` function.

```
htf.get_tags(tests="/path/to/test")
```

```
htf.get_tags(tests: Any | List[Any] = '__main__', pattern: str = 'test*.py') → List[str]
```

Get a list of tags found in the specified tests.

Parameters:

- **tests=None** – a test-specifier or a list of test-specifiers (folder, file, test-case, test-case-method, module)
- **pattern="test*.py"** – the pattern to be used when searching for python files in folders

Returns:
a list of tags found in the specified tests.
Return type:
list of str

To use tags for fixtures use the `fixture_tags` option set to an expression.

```
htf.main(fixture_tags="hardware")
```

Metadata

To add metadata about the test run use the `metadata` parameter set to a dictionary containing metadata.

This feature can be used to, for example, add information about a tested firmware version, etc.

```
metadata_dict = dict(firmware_version="1.2.3", hardware_version="4.5.6")
htf.main(metadata=metadata_dict)
```

The metadata will appear in the test reports.

Parameters

You can add parameters to test runs to control the behavior of tests and fixtures. Use the `parameters` parameter as a dict to supply parameters to test runs.

The parameters are available via the `htf.fixtures.Parameters` fixture.

```
htf.main(parameters=dict(name1="value1", name2="value2"))
```

The parameters will also appear in the test result metadata.

htf.run()

`htf.run` is an alias for `htf.main`.

```
htf.run(title: str = 'Testreport', tests: Any | List[Any] = '__main__', tags: str | None =
None, fixture_tags: str | None = None, html_report: str | List[str] | None = None,
junit_xml_report: str | List[str] | None = None, json_report: str | List[str] | None = None,
yaml_report: str | List[str] | None = None, report_server: str | List[str] | None = None,
extra_report: Any | List[Any] | None = None, create_drafts: bool = False, open_report: bool =
False, pattern: str = 'test*.py', metadata: Dict[str, Any] | None = None, parameters:
Dict[str, str] | None = None, exit: bool = True, fail_fast: bool = False,
minimize_report_size: bool = False, interactive: bool = False, interactive_address: str =
```

```
'0.0.0.0', interactive_port: int = 8080, open_browser: bool = True, shuffle: bool = False,
shuffle_seed: str | int | None = None) → int
```

Test runner.

Parameters:

- **title** – the test's title
- **tests=None** – a test-specifier or a list of test-specifiers (folder, file, test-case, test-case-method, module)
- **tags=None** – test filter expression
- **fixture_tags=None** – fixture filter expression
- **html_report=None** – HTML-report filename(s)
- **junit_xml_report=None** – JUnit-XML-report filename(s)
- **json_report=None** – JSON-report filename(s)
- **yaml_report=None** – YAML-report filename(s)
- **report_server=None** – Url or list of urls to report server
- **extra_report=None** – Extra reports that support instance.render(data). This is useful for `htf.DOORSTestReport` for example that needs additional parameters.
- **create_drafts=False** – if set to `True` draft reports are created after each test
- **open_report=False** – if set to `True` the HTML test report is opened after the test run
- **pattern="test*.py"** – the pattern to be used when searching for python files in folders
- **metadata=None** – a dictionary that contains metadata about the test run
- **parameters=None** – a dictionary that contains parameters for the test run
- **exit=True** – if set to `True` the exit() is called at the end of the tests
- **fail_fast=False** – if set to `True` the test run ends after the first failing test
- **minimize_report_size=False** – if set to `True` the report size is minimized.
- **interactive=False** – if set to `True` the tests are run interactively
- **interactive_address="0.0.0.0"** – the ip address the interaction server listens on.
- **interactive_port=8080** – the port the interaction server listens on.
- **open_browser=True** – if set to `False` browser is not opened automatically
- **shuffle=False** – set to `True` to shuffle tests
- **shuffle_seed=None** – the shuffle seed or 'last' to use the last shuffle seed

Returns:
`0` if the run was successful or the number of failed tests in case or errors and failures.
Return type:
int

htf.verify()

`htf.verify` verifies the system environment for validated installations.

```
htf.verify() → bool
```

Verify system environment. Needs `htf-validated` installed and the license feature `verification`.

Returns:
`True` in case the system environment was successfully verified else `False`
Return type:
bool

Docker Integration

Introduction

Since `htf-1.3` HILSTER supplies multi platform Docker containers for every version that can be used like the `htf` command line utility. The great advantage is that the user does not need to install and update HILSTER Testing Framework manually because Docker does this job automatically.

For example to download the latest version into Docker simply run

```
docker pull hilster/htf
```

Operation Systems

HILSTER offers Docker containers for Linux and Windows (both amd64) for the latest supported Python version and every patch release.

This documentation assumes that Windows hosts run Windows Docker containers. It is also possible to run Linux Docker containers from a Windows host. In this case the examples will not work without modification.

Tags

HILSTER supports tags for every patch version (e.g. `hilster/htf:1.3.1`, for every newest minor version (e.g. `hilster/htf:1.3`) and for every major version (e.g. `hilster/htf:1`).

The `hilster/htf:latest` or `hilster/htf` tags always point to the latest release.

We suggest to use a minor version and not the patch version to be able to automatically update to the newest patch version.

Volumes

The Docker containers have one volume to store licences. On Linux the volume is `/licenses` and on Windows it is `C:/licenses`. The volumes can also be bind mounted to the host filesystem to persist licenses.

Bind Mounts

The following bind mounts `/code` (Linux) or `C:/code` (Windows) and `/tests` (Linux) or `C:/tests` (Windows) can be used for testing.

`code` is used to supply user editable code for a project.

`tests` is used to supply user editable tests. `tests` is the working directory of the Docker containers.

PYTHONPATH

The environment variable `PYTHONPATH` includes the `code` and `tests` volumes so Python will automatically search for modules there.

Activation

To activate use the Docker only `--activate <activationkey>` option, e.g.:

```
docker run hilster/htf --activate AAAA-BBBB-CCCC-DDDD
```

The `--activate <activationkey>` option can also be added to all other options to `htf` and will be filtered out by a wrapper script that handles the activation. This way it is possible to automatically activate a node for every run for example in a continuous integration system.

Renewal

To renew licenses use the Docker only `--renew` option, e.g.:

```
docker run hilster/htf --renew
```

Interactive Mode

To run `htf` in Docker interactively enter

```
docker run hilster/htf --shell
```

SSL Verification

In some circumstances it might be necessary to disable SSL verification. To do this simply set the environment variable `HLM_INSECURE` to any value and activate or renew.

```
docker run -e HLM_INSECURE=1 hilster/htf --activate AAAA-BBBB-CCCC-DDDD
```

Command Line Utility

`hilster/htf` is used like a command line utility and uses the `htf` executable as the entry point. So the usage is exactly the same like for the `htf` command line utility.

Simply replace `htf <options>` with `docker run -it [...] hilster/htf <options>`.

You might also like to create an alias for `docker run -it [...] hilster/htf` named `htf` to be able to run `htf` in Docker like they way it would be installed locally.

Community Edition

Docker is also available for the community edition. Simply replace the tag `htf` with `htf-community`.

```
docker run hilster/htf-community
```

Examples

Running Tests

On Linux run

```
docker run -it -v $(pwd)/project:/code -v $(pwd)/tests:/tests hilster/htf
```

and on Windows run

```
docker run -it -v %cd%/project:C:/code -v %cd%/tests:C:/tests hilster/htf
```

Running Tests with Activation and persistently stored license

Lets assume you have activation key `AAAA-BBBB-CCCC-DDDD` and the node shall renew its licenses or activate itself.

Linux

Activation:

```
docker run -it \
    -v $(pwd)/project:/code \
    -v $(pwd)/tests:/tests \
    -v $(pwd)/licenses:/licenses \
    hilster/htf --activate AAAA-BBBB-CCCC-DDDD
```

Run tests with persistently stored license without activation:

```
docker run -it \
    -v $(pwd)/project:/code \
    -v $(pwd)/tests:/tests \
    -v $(pwd)/licenses:/licenses \
    hilster/htf
```

Windows

Activation:

```
docker run -it ^
    -v %cd%/project:C:/code ^
    -v %cd%/tests:C:/tests ^
    -v %cd%/licenses:C:/licenses ^
    hilster/htf --activate AAAA-BBBB-CCCC-DDDD
```

Run tests with persistently stored license without activation:

```
docker run -it ^
    -v %cd%/project:C:/code ^
    -v %cd%/tests:C:/tests ^
    -v %cd%/licenses:C:/licenses ^
    hilster/htf
```

The `--activate <activation key>` option is not an `htf` option but is handled by a wrapper script.

Running Specific Tests

Lets assume you have `tests.initial_tests` as an importable module bind mounted to `tests` and you only want to run these tests.

On Linux run

```
docker run -it -v $(pwd)/project:/code -v $(pwd)/tests:/tests hilster/htf initial_tests
```

and on Windows run

```
docker run -it -v %cd%/project:C:/code -v %cd%/tests:C:/tests hilster/htf initial_tests
```

Using Docker for a Project with Dependencies

Often you need to add some dependencies for your project stored in `requieements.txt`. If you need requirements and want to use Docker for testing you can create your own Docker container based on `hilster/htf`.

To do this create a file `requirements.txt` with your requirements for example

```
numpy
matplotlib
scipy
```

Create a `Dockerfile` with contents like

```
FROM hilster/htf
MAINTAINER HILSTER <mail@hilster.io>

ADD requirements.txt requirements.txt
RUN pip install -r requirements.txt
```

This will add `requirements.txt` to your container and will install the dependencies while being built.

To build and tag your Docker container simply run

```
docker build -t <project_name> .
```

To run your container simply run

```
docker run -it -v $(pwd)/project:/code -v $(pwd)/tests:/tests <project_name>
```

on Linux and

```
docker run -it -v %cd%/project:C:/code -v %cd%/tests:C:/tests <project_name>
```

on Windows.

Mapping Comports

To map a comport on a Linux host use the `--device` option.

The following example shows how to map `/dev/ttyUSB0` to the Docker container.

```
docker run -it --device=/dev/ttyUSB0 hilster/htf
```

On Windows devices have a different description in form of `<IdType>/><Id>`.

The following example maps a comport to the Docker container.

```
docker run -it --device="class/86E0D1E0-8089-11D0-9CE4-08003E301337" hilster/htf
```

Mapping USB Dongles

On Linux map `/sys/bus/usb/devices` into the Docker container and use the `--privileged` option to be able to use USB dongles from within the container.

```
docker run -it --privileged -v /sys/bus/usb/devices:/sys/bus/usb/devices hilster/htf
```

On Windows you have to add the corresponding USB device to be handled by the Docker container.

Dry Run

The dry run feature is supported by the HILSTER Testing Framework since version `htf-1.2`.

The dry run feature works like a normal test run but marks all tests to be skipped and is fast as a result.

This is useful feature if you want check your test selection with or without tagging. It can also be used to easily create a test specification if your test specifications are included in the docstring of your tests.

The test specification can be read within an HTML-report or you can use a JSON-report to create another document using the contained data.

htf.dryrun()

`htf.dryrun` can be used to do a dry run of a test suite from a Python script. It accepts the same parameters as `htf.main` and `htf.run` do and so it can easily be substituted.

```
htf.dryrun(title: str = 'Testreport', tests: Any | List[Any] = '__main__', tags: str | None =
None, fixture_tags: str | None = None, html_report: str | List[str] | None = None,
junit_xml_report: str | List[str] | None = None, json_report: str | List[str] | None = None,
yaml_report: str | List[str] | None = None, report_server: str | List[str] | None = None,
extra_report: Any | List[Any] | None = None, create_drafts: bool = False, open_report: bool =
False, pattern: str = 'test*.py', metadata: Dict[str, Any] | None = None, parameters:
Dict[str, str] | None = None, exit: bool = True, fail_fast: bool = False,
minimize_report_size: bool = False, interactive: bool = False, interactive_address: str =
'0.0.0.0', interactive_port: int = 8080, open_browser: bool = True, shuffle: bool = False,
shuffle_seed: str | int | None = None) → int
```

Test runner for a dry run to watch the test suite.

Parameters:

- **title** – the test's title
- **tests=None** – a test-specifier or a list of test-specifiers (folder, file, test-case, test-case-method, module)

- **ags=None** – test filter expression
- **fixture_tags=None** – fixture filter expression
- **html_report=None** – HTML-report filename(s)
- **junit_xml_report=None** – JUnit-XML-report filename(s)
- **json_report=None** – JSON-report filename(s)
- **yaml_report=None** – YAML-report filename(s)
- **report_server=None** – Url or list of urls to report server
- **extra_report=None** – Extra reports that support instance.render(data). This is useful for `htf.DOORSTestReport` for example that needs additional parameters.
- **create_drafts=False** – if set to `True` draft reports are created after each test
- **open_report=False** – if set to `True` the HTML test report is opened after the test run
- **pattern="test*.py"** – the pattern to be used when searching for python files in folders
- **metadata=None** – a dictionary that contains metadata about the test run
- **parameters=None** – a dictionary that contains parameters for the test run
- **exit=True** – if set to `True` the exit() is called at the end of the tests
- **fail_fast=False** – if set to `True` the test run ends after the first failing test
- **minimize_report_size=False** – if set to `True` the report size is minimized.
- **interactive=False** – if set to `True` the tests are run interactively
- **interactive_address="0.0.0.0"** – the ip address the interaction server listens on.
- **interactive_port=8080** – the port the interaction server listens on.
- **open_browser=True** – if set to `False` browser is not opened automatically
- **shuffle=False** – set to `True` to shuffle tests
- **shuffle_seed=None** – the shuffle seed or 'last' to use the last shuffle seed

Returns:
`0` if the run was successful or the number of failed tests in case or errors and failures.
Return type:
int

htf dryrun

To dry run from command line use `htf dryrun ...`. It accepts the same parameters as `htf run` does and so it can easily be substituted.

Tagging

Tagging allows you to attach arbitrary labels to testcases and tests which can then be selected using a logical expression.

Tagging is a very useful feature to group tests or to partition and paralell long running test suites easily without any additional effort.

Adding tags to testcases and tests

Tagging is done using the `htf.tags` decorator which can be used for testcases and tests. Tests inherit the tags from the testcase they are located in. Inherited tags are merged with local tags.

```
import htf

@htf.tags("foo")
class TestFoo(htf.TestCase):

    @htf.tags("one")
    def test_one(self):
        pass

    @htf.tags("two")
    def test_two(self):
        pass

    @htf.tags("three", "io")
    def test_three(self):
        # use io
        pass

@htf.tags("bar")
class TestBar(htf.TestCase):

    @htf.tags("one")
    def test_one(self):
        pass

    @htf.tags("two")
    def test_two(self):
        pass

    @htf.tags("three", "io")
    def test_three(self):
        # use io
        pass
```

All tests in `TestFoo` are tagged with `"foo"` and all tests in `TestBar` are tagged with `"bar"`.

Logical expression to select tags

Tagged tests can be selected using a logical expression that is evaluated to find matching tests.

A logical expression is a string consisting of tag names, operators and pairs of brackets.

The parser supports the following tokens:

Token	Description
tag	A string matching the regular expression `r'[a-zA-Z0-9_\-\.\=]+'`. So it consists of `a..z`, `A-Z` `0..9`, `_`, `-`, `=` and `.`.
&	Logical and
|	Logical or
^	Logical xor
!	Logical not
(	Left bracket
)	Right bracket

Groups are built using the brackets. Groups are evaluated first.

Whitespaces are ignored.

For example to select all tests that have the `"foo"` tag the logical expression would be `"foo"`.

To select all tests that do not have the `"foo"` tag the logical expression would be `"!foo"`.

To select all tests that uses `"io"` and `"bar"` the expression is `"io&bar"` (or `"io & bar"` for better readability).

To select all tests that are tagged with `"bar"` or `"io"` and `"three"` the expression is `"bar | (io & three)"`.

Selecting tests using tags

To select tests using a logical expression and tags is easy.

`htf.main`, `htf.run` and `htf.dryrun` have the `tags` option set to a logical expression.

For example:

```
htf.main(tags="bar | (io & three)")
```

For the command line utilities `htf run` and `htf dryrun` use the `-t` or `--tags` option followed by a logical expression.

For example:

```
htf run --tags='bar | (io & three)'
```

Showing available tags

To get a list of available tags you can use `$ htf tags` from the command line or `htf.get_tags` from within a Python script.

For the initial example this would lead to a sorted list of tags consisting of `bar`, `foo`, `io`, `one`, `three` and `two`.

Data Driven Testing

Data Driven Testing allows dynamic generation of tests using a data source. The data source can be Python objects, JSON, CSV or YAML files.

To use Data Driven Testing simply decorate tests using the data or combinatoric decorators as mentioned below.

Code-based Examples

Full Example

In the following example the test function is called three times with a value from a list of scalars. To use data driven testing in `htf` the test methods are decorated with the decorator supplying the data values.

```
import htf

@htf.data([1.0, 2.0, 3.0])
def test_scalar(value):
    print("value:", value)

if __name__ == "__main__":
    htf.main()
```

List of Scalars

The following examples demonstrate the usage of Python objects as data input. The decorator to be used when the data is supplied as a Python object is `@htf.data(<object>)`.

The following example uses a list of integers as data.

```
@htf.data([23, 24, 25])
def test_scalar(value):
    print("value:", value)

# generates calls
# test_scalar(value=23)
# test_scalar(value=24)
# ...
```

Iterator

An iterator can also be supplied.

```
@htf.data(iter([23, 24, 25]))
def test_iterator(value):
    print("value:", value)
```

Generator

It is also possible to supply a generator.

```
def generator() -> Generator[int, None, None]:
    yield 10
    yield 20
    yield 30
```

```
@htf.data(generator())
def test_generator_instance(value):
    print("value:", value)

# generates calls
# test_generator_instance(value=10)
# test_generator_instance(value=20)
# ...

@htf.data(generator)
def test_generator(value):
    print("value:", value)

# generates calls
# test_generator(value=10)
# test_generator(value=20)
# ...
```

Async generators are supported, too.

```
async def generator() -> AsyncGenerator[int, None]:
    yield 10
    yield 20
    yield 30

@htf.data(generator())
async def test_generator_instance(value):
    print("value:", value)
```

List of Dicts

The following example supplies a list of dictionaries. The number of parameters must match the number of dictionary entries.

```
@htf.data([dict(a=23, b=1), dict(a=24, b=2), dict(a=25, b=3)])
def test_dict(a, b):
   print("a:", a, "b:", b)

# generates calls
# test_dict(a=23, b=1)
# test_dict(a=24, b=2)
# ...
```

List of Lists

Lastly it is also possible to supply lists of lists. When called, `value` contains a list.

```
@htf.data([[1, 2, 3], [4, 5, 6]])
def test_list_of_int(value):
    print("value:", value)
```

```
# generates calls
# test_list_of_int(value=[1, 2, 3])
# ...

@htf.data([[dict(value=23)], [dict(value=24)], [dict(value=25)]])
def test_list_of_lists_of_dict(values):
   print("value:", values)

# generates calls
# test_list_of_lists_of_dict(value=23)
# test_list_of_lists_of_dict(value=24)
# ...
```

Unpack the content of `value` by setting `unpack=True` to distribute the list entries to three parameters.

```
@htf.data([[1, 2, 3], [4, 5, 6]], unpack=True)
def test_list_of_int_unpack(a, b, c):
    print("a:", a, "b:", b, "c:", c)

# generates
# test_list_of_int_unpack(a=1, b=2, c=3)
# ...
```

File-based Examples

The following examples demonstrate the usage of various file formats as data input. The supported file formats and their corresponding decorators are:

File type	Decorator
JSON-file	`@htf.json_data("filename.json")`
YAML-file	`@htf.yaml_data("filename.yml")`
CSV-file	`@htf.csv_data("filename.csv")`

In each case there is also the option of first creating an iterator for the file content which is handed to the `@htf.data()` decorator. For this purpose the following syntax is used:

File type	Decorator and Iterator
JSON-file	`@htf.data(htf.JSONFileIterator("filename.json"))`
YAML-file	`@htf.data(htf.YAMLFileIterator("filename.yml"))`
CSV-file	`@htf.data(htf.CSVFileIterator("filename.csv"))`

Furthermore, decorators for JSON and YAML input have the option `unpack` set to `False` by default. If changed to `True` lists will be unpacked as demonstrated in the below examples. There is no such option for the CSV decorator.

JSON Test Data

To supply simple scalar values as data from a JSON file, use the following code:

```
@htf.json_data("ddt_scalar.json")
def test_json_scalar(value):
    print("value: ", value)

# generates calls
# test_json(value=1337)
# test_json(value=1338)
# ...

@htf.data(htf.JSONFileIterator("ddt_scalar.json"))
def test_json_iterator(value):
    print("value:", value)

# generates calls
# test_json_iterator(value=1337)
# test_json_iterator(value=1338)
# ...
```

Contents of `ddt_scalar.json`:

```
[1337, 1338, 1339]
```

If the supplied data comes in form of nested lists, `unpack` can be set to `True` to assign each inner list element to a variable.

```
@htf.json_data("ddt_list.json", unpack=True)
def test_json_list_unpack(a, b, c):
    print("value: ", a, b, c)

# generates calls
# test_json_list(a=111, b=222, c=333)
# test_json_list(a=11, b=22, c=33)
# ...

@htf.json_data("ddt_list.json", unpack=False)
def test_json_list(value):
    print("value: ", value)

# generates calls
# test_json_list(value=[111, 222, 333])
# test_json_list(value=[11, 22, 33])
# ...
```

Contents of `ddt_list.json`:

```
[[1,2,3], [11,22,33], [111,222,333]]
```

YAML Test Data

Supplying scalar values as data from a YAML file works analogously to JSON files.

```
@htf.yaml_data("ddt_scalar.yml")
def test_yaml_scalar(value):
    print("value:", value)

# generates calls
# test_yaml(value=1337)
# test_yaml(value=1338)
# ...

@htf.data(htf.YAMLFileIterator("ddt_scalar.yml"))
def test_yaml_iterator(value):
    print("value:", value)

# generates calls
# test_yaml_iterator(value=1337)
# test_yaml_iterator(value=1338)
# ...
```

Contents of `ddt_scalar.yml`:

```
[1337, 1338, 1339]
```

The following code showcases the use of the `unpack` option in the case of a YAML file.

```
@htf.yaml_data("ddt_list.yml", unpack=True)
def test_yaml_list_unpack(a, b, c):
    print("value: ", a, b, c)

# generates calls
# test_yaml_list(a=111, b=222, c=333)
# test_yaml_list(a=11, b=22, c=33)
# ...

@htf.yaml_data("ddt_list.yml", unpack=False)
def test_yaml_list(value):
    print("value: ", value)

# generates
# test_yaml_list(value=[111, 222, 333])
# test_yaml_list(value=[11, 22, 33])
# ...
```

Contents of `ddt_list.yml`:

```
[[1,2,3], [11,22,33], [111,222,333]]
```

CSV Test Data

Tests can also be generated using CSV data sources. The first line of the CSV data is a header. The parameter names of the decorated method must match the entries of the header, i.e. the fist line of each column must contain the name of the parameter to which the data is to be assigned. Each line is supplied as a `dict`. Note that the entries of the `dict` are strings by default.

```
@htf.csv_data("ddt.csv")
def test_csv(a, b):
    print("a: ", a, "b: ", b)

# generates calls
# test_csv(a=1337, b=2222)
# a: 1337 b: 2222
# test_csv(a=1338, b=3333)
# a: 1338 b: 3333
# ...

@htf.data(htf.CSVFileIterator("ddt.csv"))
def test_csv_iterator(a, b):
    print("a: ", a, "b: ", b)

# generates calls
# test_csv(a=1337, b=2222)
# a: 1337 b: 2222
# test_csv(a=1337, b=3333)
# a: 1338 b: 3333
# ...
```

Contents of `ddt.csv`:

```
a,b
1337,2222
1338,3333
1339,4444
```

CSV data source values are not converted automatically. The desired conversion can be specified with the optional `convert_to` parameter. `convert_to` can be a callable or list thereof. If conversion fails with a ValueError the value is passed as a string.

```
@htf.csv_data("ddt.csv", convert_to=[int, float])
def test_csv(a, b):
    print("a: ", a, "b: ", b)

# generates calls
# test_csv(a=1337, b=2222.0)
# a: 1337 b: 2222.0
# test_csv(a=1338, b=3333.0)
# a: 1338 b: 3333.0
# ...
```

Combinatoric Data Generation

Combinatoric decorators can be used to manipulate the supplied data.

Cartesian Product

The `product` function produces every possible combination of items, taking one item of each given iterable.

```
@htf.product([1, 2, 3], repeat=2)
def test_product(a, b):
    print("a:", a, "b:", b)

# generates calls
# test_product(a=1, b=1)
# test_product(a=1, b=2)
# ...

@htf.product([1, 2], [3, 4], repeat=1)
def test_products(a, b):
    print("a:", a, "b:", b)

# generates calls
# test_products(a=1, b=3)
# test_products(a=2, b=3)
# ...
```

In combination with the aforementioned file iterator functions, this can be used to produce combinations of elements of given data files.

```
@htf.product(htf.JSONFileIterator("ddt_scalar.json"), repeat=2)
def test_json_products(a, b):
    print("a:", a, "b:", b)

# generates calls
# test_products(a=1337, b=1337)
# test_products(a=1337, b=1338)
# ...

@htf.product(list(range(10)), repeat=3)
def test_long_products(*args):
    print("args:", args)

# generates calls
# test_long_products(*(0, 0, 1))
# test_long_products(*(0, 0, 2))
# ...
```

Permutations

The `permutations` function creates all permutations of length `r` of a given iterable.

```
@htf.permutations([1, 2, 3], r=2)
def test_permutations(a, b):
    print("a:", a, "b:", b)

# generates calls
# test_permutations(a=1, b=2)
# test_permutations(a=1, b=3)
# ...
```

Combinations

The `combinations` function produces all possible combinations of elements of an iterable without changing their order. Elements are not combined with themselves.

```
@htf.combinations([1, 2, 3], r=2)
def test_combinations(a, b):
    print("a:", a, "b:", b)

# generates calls
# test_combinations(a=1, b=2)
# test_combinations(a=1, b=3)
# ...
```

The `combinations_with_replacement` function does the same as the combinations function, except elements are also combined with themselves.

```
@htf.combinations_with_replacement([1, 2, 3], r=2)
def test_combinations_with_replacement(a, b):
    print("a:", a, "b:", b)

# generates calls
# test_combinations_with_replacement(a=1, b=1)
# test_combinations_with_replacement(a=1, b=2)
# ...
```

Data Decorators

```
htf.data(iterable: Iterable, unpack: bool = False) → Callable[[Callable[[...], Any]], Any]
```

Create a data driven test using data.

Parameters:

- **iterable** – an iterable used as parameter data source. Can also be a callable.
- **unpack=False** – if set to `True` iterables are unpacked.

```
htf.csv_data(filename: str, convert_to: Iterable[Any] | Generator[Any, None, None] |
List[Any] | Any | None = None) → Callable[[Callable[[...], Any]], Any]
```

Create a data driven test using data from a CSV file. The first line of the CSV data is a header. Each column from the first is used as the parameter name of the decorated method. Each line is supplied as a `dict`.

Parameters:

- **filename** – the filename to be read.
- **convert_to** – data types to convert read values to (e.g. float, int)

```
htf.yaml_data(filename: str, unpack: bool = False) → Callable[[Callable[[...], Any]], Any]
```

Create a data driven test using data from a YAML file.

Parameters:

- **filename** – the filename to be read.
- **unpack=False** – if set to `True` iterables are unpacked.

```
htf.json_data(filename: str, unpack: bool = False) → Callable[[Callable[[...], Any]], Any]
```

Create a data driven test using data from a json file.

Parameters:

- **filename** – the filename to be read.
- **unpack=False** – if set to `True` iterables are unpacked.

Combinatoric Decorators

```
htf.product(*iterables: Iterable, **repeat: int) → Callable[[Callable[[...], Any]], Any]
```

Create a data driven test using `itertools.product` with a cartesian product of input `*iterables`.

Parameters:

- ***iterables** – iterables to be passed to `itertools.product`
- **repeat=1** – number of repetitions.

```
htf.permutations(iterable: Iterable, r: int | None = None) → Callable[[Callable[[...],
Any]], Any]
```

Create a data driven test using `itertools.permutations` with successive `r` length permutations of elements in the `iterable`.

Parameters:

- **iterable** – iterable to be passed to `itertools.permutations`
- **r=None** – length of permutations

```
htf.combinations(iterable: Iterable, r: int) → Callable[[Callable[[...], Any]], Any]
```

Create a data driven test using `itertools.combinations` with successive `r` length subsequences of elements from `iterable`.

Parameters:

- **iterable** – iterable to be passed to `itertools.combinations`
- **r** – length of combinations

```
htf.combinations_with_replacement(iterable: Iterable, r: int) → Callable[[Callable[[...],
Any]], Any]
```

Create a data driven test using `itertools.combinations` with successive `r` length subsequences of elements from `iterable` allowing individual elements to be repeated more than once.

Parameters:

- **iterable** – iterable to be passed to `itertools.combinations_with_replacement`
- **r** – length of combinations

File Iterators

```
class htf.CSVFileIterator(filename: str, convert_to: Iterable[Any] | Generator[Any, None,
None] | List[Any] | Any | None = None)
```

CSV file iterator.

Parameters:
filename – the filename to be read.
Returns:
iterator for the file contents as `dict`. convert_to: data types to convert read values to (e.g. float, int)
Return type:
iterator

```
class htf.YAMLFileIterator(filename: str)
```

YAML file iterator.

Parameters:
filename – the filename to be read.
Returns:
iterator for the file contents.

Return type:
iterator

```
class htf.JSONFileIterator(filename: str)
```

JSON file iterator.

Parameters:
filename – the filename to be read.
Returns:
iterator for the file contents.
Return type:
iterator

Interactive Testing

In some circumstances not all tests can be completely automated.

htf offers interactive testing which allows you to interact with your tests via your web browser. A web server is started on port `8080`.

A QR code is printed on the terminal so that you can interact using your mobile phone or a tablet easily.

This feature can be used to script and revision manual tests for example.

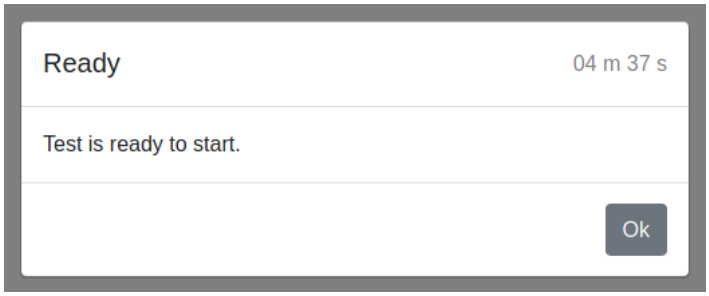
Interaction is done via the `interaction` fixture.

htf needs to run in interactive mode. When running from command line add the `-i` argument or set `interactive=True` in `htf.main`.

By default a browser is opened to be used for interaction. If you do not wish to open the browser automatically use `--no-browser` or pass `open_browser=False` to `htf.main`.

To set the listening address use `--interactive-address` or `interactive_address` in `htf.main` To set the port to listen on use `--interactive-port` or `interactive_port` in `htf.main`.

All interaction dialogs will be put into the HTML test report with the appropriate answers.



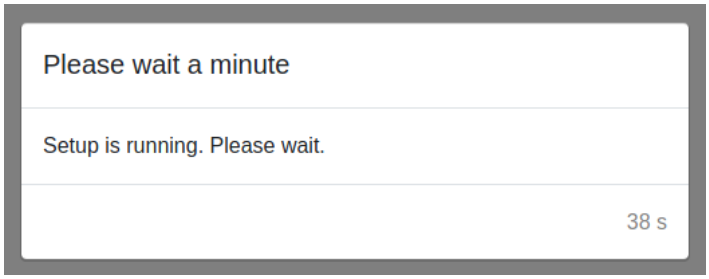
Interaction Dialogs

Message Dialog

To inform the user you can create a `message_dialog`. The message dialog has an ok button that will hide it immediately.

```
def test_message_dialog(interaction):
    """
    This test shows how to use a message dialog.
```

```
    Args:
        interaction (htf.fixtures.interaction): the interaction fixture
    """
    interaction.message_dialog("Ready", "Test is ready to start.")
```

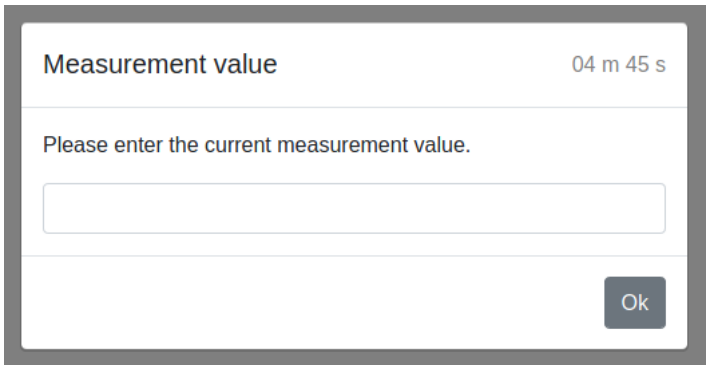


Waiting Dialog

To let the user wait for a given time you can use `waiting_dialog`. The timeout must not be `None`.

```
def test_waiting_dialog(interaction):
    """
    This test shows how to use a waiting dialog.

    Args:
        interaction (htf.fixtures.interaction): the interaction fixture
    """
    interaction.waiting_dialog("Please wait a minute", "Setup is running. Please wait.", timeout=60)
```



Input Dialog

If your test needs user input you can use `input_dialog`.

```
def test_input_dialog(interaction):
    """
    This test shows how to use an input dialog.

    Args:
        interaction (htf.fixtures.interaction): the interaction fixture
    """
    value = interaction.input_dialog("Measurement value", "Please enter the current measurement
value.")
    # value is a string
```

You can optionally validate the user's inputs on server side that only valid inputs are accepted. The validator can also act as a type cast.

```
def test_input_dialog(interaction):
    """
    This test shows how to use an input dialog with a float validator.

    Args:
        interaction (htf.fixtures.interaction): the interaction fixture
    """
    value = interaction.input_dialog("Measurement value", "Please enter the current measurement
value.",
                           validator=htf.float_validator)
    # value is a float
```

There are some built-in validators.

```
htf.int_validator(value: Any) → int
```

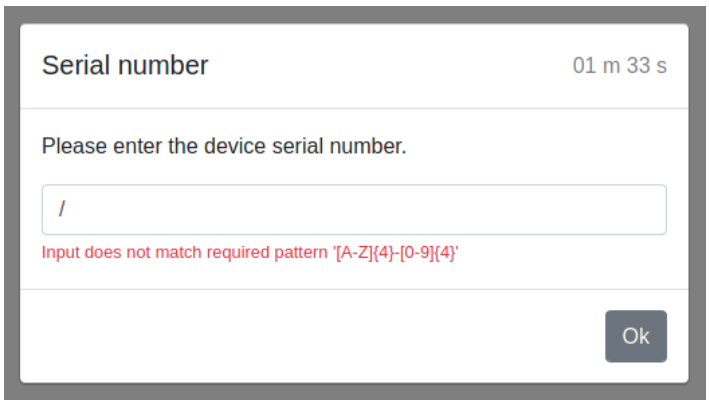
An int validator for interactive tests.

```
htf.float_validator(value: Any) → float
```

A float validator for interactive tests.

```
htf.regex_validator(pattern: str, exception_message: str | None = None) → Callable[[str],
str]
```

A regex validator factory.



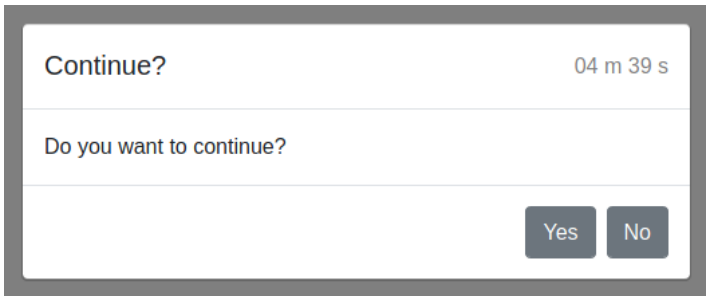
Parameters:

- **pattern** – the regex pattern to be checked
- **exception_message=None** – the optional exception message supplied to the user in its browser

Returns:
an interaction validator for pattern

```
def test_input_dialog(interaction):
    """
    This test shows how to use an input dialog with a regex validator.

    Args:
        interaction (htf.fixtures.interaction): the interaction fixture
    """
    value = interaction.input_dialog("Serial number", "Please enter the device serial number.",
                         validator=htf.regex_validator(pattern=r"[A-Z]{4}-[0-9]{4}"))
    # value is a valid serial number
```

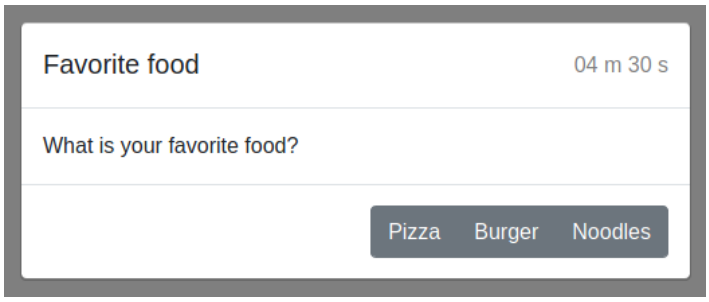


Yes-No Dialog

To ask the user a yes-no question you can use `yes_no_dialog`.

```
def test_yes_no_dialog(interaction):
    """
    This test shows how to use a yes-no dialog.

    Args:
        interaction (htf.fixtures.interaction): the interaction fixture
    """
    value = interaction.yes_no_dialog("Continue?", "Do you want to continue?")
    # value is 'yes' or 'no' or None in case of a timeout
```

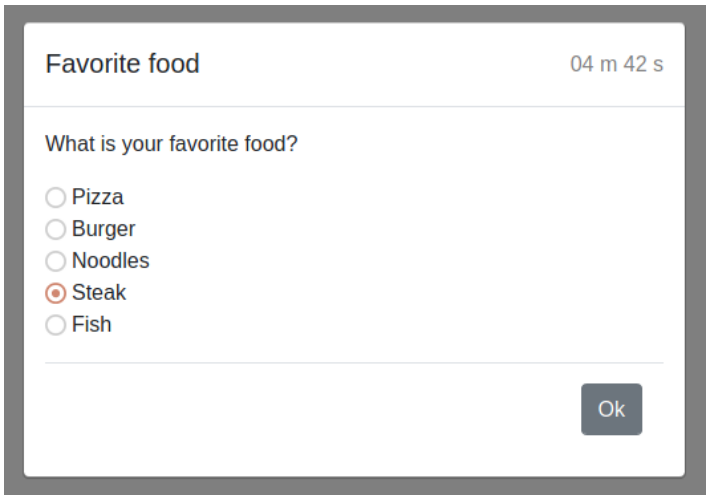


Button Dialog

To ask the user a question with one answer out of multiple predefined choices you can use the `button_dialog`.

```
def test_button_dialog(interaction):
    """
    This test shows how to use a button dialog.

    Args:
        interaction (htf.fixtures.interaction): the interaction fixture
    """
    value = interaction.button_dialog("Favorite food", "What is your favorite food?",
                                      choices=[
                                          ("Pizza", "pizza"),
                                          ("Burger", "burger"),
                                          ("Noodles", "noodles"),
                                      ])
    # value is 'pizza', 'burger', 'noodles' or None in case of a timeout
```

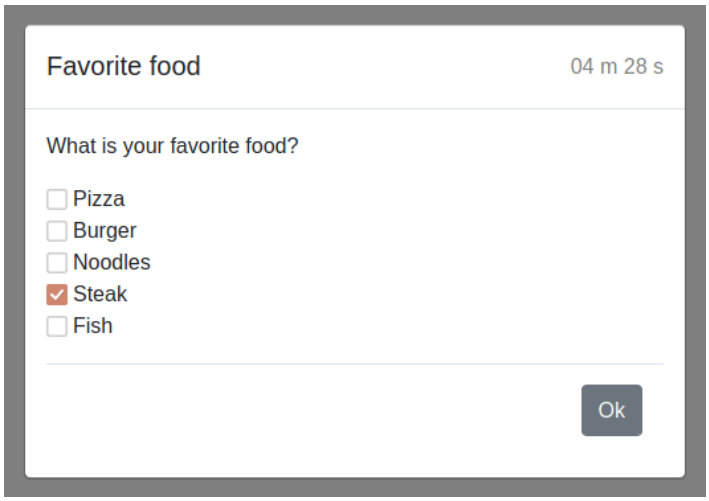


Radio Button Dialog

To ask the user a question with one answer out of multiple predefined choices you can use the `radio_button_dialog`.

```
def test_radio_button_dialog(interaction):
    """
    This test shows how to use a radio button dialog.

    Args:
        interaction (htf.fixtures.interaction): the interaction fixture
    """
    value = interaction.radio_button_dialog("Favorite food", "What is your favorite food?",
                choices=[
                    "Pizza",  # label and answer are the same
                    ["Burger", "burger"],  # label is left and answer is right
                    ("Noodles", "noodles"),  # supplied as a tuple
                    ["Steak", True],  # label and answer are the same and the checkbox is checked
                    ["Fish", "fish", False]
#  # label is left and answer is right and the checkbox is not checked
                ])
    # value is 'Pizza', 'burger', 'noodles', 'Steak', 'fish' or None in case of a timeout
```

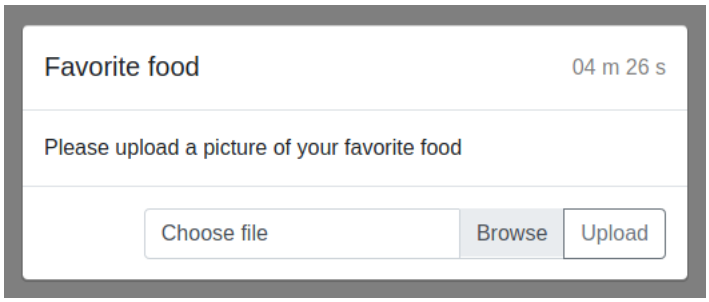


Checkbox Dialog

To ask the user a question with multiple predefined answers you can use the `checkbox_dialog`.

```
def test_checkbox_dialog(interaction):
    """
    This test shows how to use a checkbox dialog.

    Args:
        interaction (htf.fixtures.interaction): the interaction fixture
    """
    value = interaction.checkbox_dialog("Favorite food", "What is your favorite food?",
                choices=[
                    "Pizza",  # label and answer are the same
                    ["Burger", "burger"],  # label is left and answer is right
                    ("Noodles", "noodles"),  # supplied as a tuple
                    ["Steak", True],  # label and answer are the same and the checkbox is checked
                    ["Fish", "fish", False]
#  # label is left and answer is right and the checkbox is not checked
                ])
    # value is a list containing no elements or multiple choices from
    # 'Pizza', 'burger', 'noodles', 'Steak', 'fish' or None in case of a timeout
```



File Upload Dialog

To allow the user to upload a file you can use the `file_upload_dialog`.

```
def test_file_upload_dialog(interaction):
    """
    This test shows how to use a file_upload dialog.

    Args:
        interaction (htf.fixtures.interaction): the interaction fixture
    """
    value = interaction.file_upload_dialog("Favorite food", "Please upload a picture of your
favorite food", ".png, image/*")
    # value is a tuple( file name, file type, uploaded file in binary form) or None in case of a
timeout.
```

Captcha Functionality

Using the `captcha` library allows you to simulate Captcha functionality in dialogs.

```
def test_solve_captchas(interaction, assertions):
    """
    This test shows how to interactively solve captchas.

    Args:
         interaction (htf.fixtures.interaction): the interaction fixture
         assertions (htf.fixtures.assertions): the assertions fixture
    """
    try:
        for number_solved in range(1, 6):  # max 5 captchas can be solved
            image = ImageCaptcha()
            captcha_value = str(randint(1000, 10000))
            image.write(captcha_value, 'captcha.png')

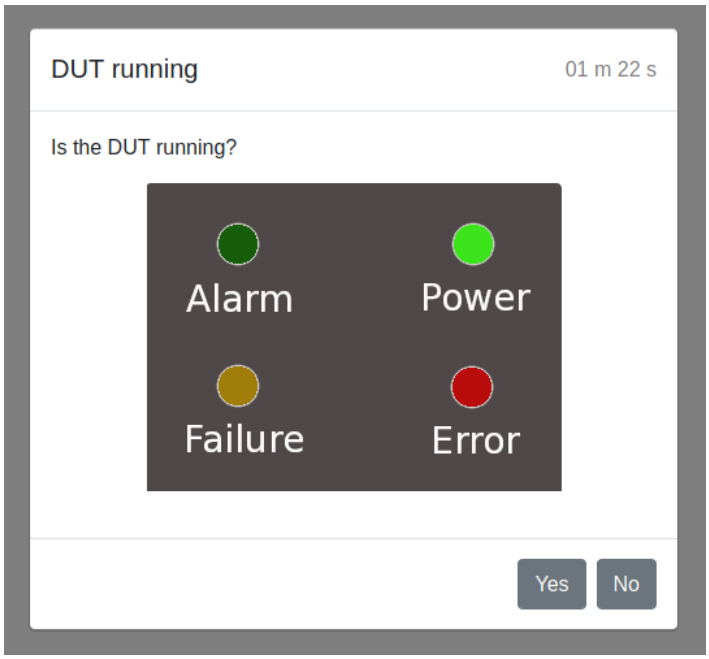
            captcha = """

            .. |captcha| image:: captcha.png
            """

            answer = interaction.input_dialog(title='Captcha',
                                              text="Please solve the following captcha:\n\n|
captcha|" + captcha)
            assertions.assert_equal(answer, captcha_value)
            if number_solved < 5:
                again = interaction.yes_no_dialog(title='Again',
```

```
                                                text="Would you like to solve another one?")
                if again == 'no':  # stop if the user has had enough
                    break
    except AssertionError:
        number_solved -= 1
        raise
    finally:
        interaction.message_dialog(title='Congratulations', text="You solved {}
captchas!".format(number_solved))
```

Embed Images in Dialogs



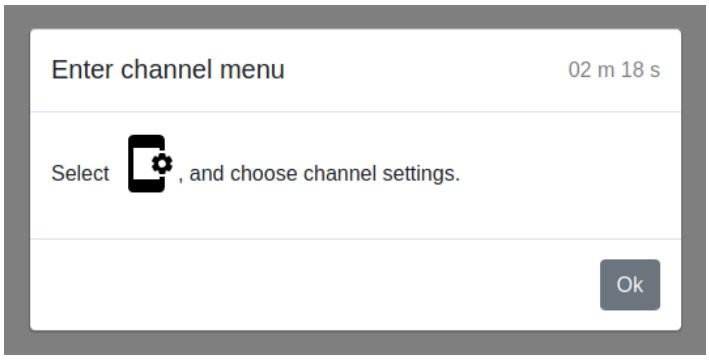
The `text` parameter of all dialogs can be reStructuredText. It is possible to embed images that appear in the dialog and in the HTML test report.

Images can be embedded as a paragraph or inline.

Images as Paragraphs

To add an image as a paragraph use

```
.. image:: path/to/image.png
```



Inline Images

To add an image inline use substitution definitions.

```
This |inlineimage| is located inline.

.. |inlineimage| image:: path/to/image.png
```

Repeat or Cancel Tests

On the top right corner in the browser a test control panel can be found. Users can repeat or cancel a test by clicking the corresponding button and entering a message.

> **Note**
>
> Cancelling or repeating a test is performed in the same thread in which the test is executed. Thus, a test can block the reaction (e.g. if it runs `time.sleep` or any other blocking call). The task of waiting for a longer time should therefore be split into several shorter calls to `time.sleep`, etc.

Reference

```
class htf.fixtures.interaction(interaction_server: BrowserInteractionServer, result:
TestResult)
```

```
button_dialog(title: str, text: str, choices: List[str] | Tuple[str], timeout: float =
300) → Any
```

Create a dialog with buttons and definable answers.

Parameters:

- **title** – the title of the button dialog
- **text** – the content of the button dialog
- **choices** – each choice can be a string containing the label and the answer a tuple or list of two strings where the first entry is the label and the second label is the answer.
- **timeout=300** – the timeout until the button dialog disappears in seconds (`None` means no timeout)

Returns:
the answer for the clicked button or `None` in case of a timeout
Return type:
object or None

```
checkbox_dialog(title: str, text: str, choices: List[str] | Tuple[str], timeout: float =
300) → Any
```

Create a dialog with definable checkboxes for multiple choices.

Parameters:

- **title** – the title of the checkbox dialog
- **text** – the content of the checkbox dialog
- **choices** – each choice can be a string containing the label and the answer a tuple or list of two strings where the first entry is the label and the second label is the answer. You can also supply a list or tuple with two entries where the first entry is the label and the second entry is a boolean that states if the radio button is checked. You can also supply a list or tuple with three entries where the first entry is the label, the second entry is the answer and the third entry is a boolean that states if the radio button is checked.
- **timeout=300** – the timeout until the checkbox dialog disappears in seconds (`None` means no timeout)

Returns:
a list containing the selected answers or `None` in case of a timeout
Return type:
list of str or None

```
file_upload_dialog(title: str, text: str, file_types: str | None = None, timeout: float
= 300) → File | None
```

Create a dialog which allows the user to upload a file.

Parameters:

- **title** – the title of the file upload dialog
- **text** – the content of the file upload dialog
- **file_types** – desired file type of files to be uploaded. This should be respected by the file chooser in all modern browsers. File types can be specified as file extensions or MIME types, with every entry separated by a comma.
- **timeout=300** – the timeout until the file upload dialog disappears in seconds (`None` means no timeout)

Returns:
tuple of str or tuple or None. `( file name, file type, uploaded file in binary form)`.

```
input_dialog(title: str, text: str, timeout: float = 300, validator: Callable[[...], Any]
| None = None) → Any
```

Create an input dialog to let the user interact with some textual input.

Parameters:

- **title** – the title of the input dialog
- **text** – the content of the input dialog
- **timeout=300** – the timeout until the input dialog disappears in seconds (`None` means no timeout)
- **validator=None** – the validator to validate the inputs on server side

Returns:
the string the user supplied, the return value of the validator or `None`
in case of a timeout

Return type:
object or None

```
message_dialog(title: str, text: str, timeout: float = 300) → Any
```

Create an interactive message dialog to display a message.

Parameters:

- **title** – the title of the message dialog
- **text** – the content of the message dialog:
- **timeout=300** – the timeout until the message dialog disappears in seconds (`None` means no timeout)

Returns:
`"ok"` in case of a click on the ok button or `None` in case of a timeout.

```
radio_button_dialog(title: str, text: str, choices: List[str] | Tuple[str], timeout:
float = 300) → Any
```

Create a dialog with definable radio buttons to select one answer out of many choices.

Parameters:

- **title** – the title of the radio button dialog
- **text** – the content of the radio button dialog
- **choices** – each choice can be a string containing the label and the answer a tuple or list of two strings where the first entry is the label and the second label is the answer. You can also supply a list or tuple with two entries where the first entry is the label and the second entry is a boolean that states if the radio button is checked. You can also supply a list or tuple with three entries where the first entry is the label, the second entry is the answer and the third entry is a boolean that states if the radio button is checked.
- **timeout=300** – the timeout until the radio button dialog disappears in seconds (`None` means no timeout)

Returns:
the answer for the selected radio button or `None` in case of a timeout
Return type:
str or None

```
waiting_dialog(title: str, text: str, timeout: float) → Any
```

Create a waiting dialog.

Parameters:

- **title** – the title of the waiting dialog
- **text** – the content of the waiting dialog
- **timeout** – the timeout until the waiting dialog disappears in seconds

Returns:
`'Ok'` after the timeout is over.

```
yes_no_dialog(title: str, text: str, timeout: float = 300) → Any
```

Create a yes-no dialog to ask the user a question.

Parameters:

- **title** – the title of the yes-no dialog
- **text** – the content of the yes-no dialog
- **timeout=300** – the timeout until the yes_no_dialog disappears in seconds (`None` means no timeout)

Returns:
`'yes'` or `'no'` depending on the user input or `None` in case of a timeout
Return type:
str or None

Settings

`htf.Settings` is used to store and modify local settings that can easily be used within your test cases or components. The local settings are stored in JSON or YAML format. JSON is the default format. YAML is assumed if the settings file extension is `.yml` or `.yaml`.

If no `filename` parameter is given and no `htf.Settings` instance exists the settings file is searched for using the following algorithm.

First the environment variable `$HTF_SETTINGS` is checked. If it does not exist or settings cannot be loaded, settings are searched for in `$HOME` and the current working directory. The expected file name is `settings` followed by the extensions `.txt`, `.json`, `.yml` or `.yaml`.

The first file that exists is loaded. If it contains errors no settings are loaded and an exception is raised.

`htf.Settings` behaves like a dictionary. So you can read and write values by keys, update it and iterate items. It is also possible to access keys without indexing like these were normal attributes

```
assert settings["key"] == settings.key  # True
```

It can be pretty-printed, too to inspect its contents.

`htf.Settings` is a singleton. This means that the settings are loaded once and every other created instance is always the same.

If you want distinct instances use `htf.SettingsNoSingleton` which offer the same behaviour without being a singleton.

JSON Example

A JSON settings file named `settings.json` and the contents

```
{
    "comport": "/dev/ttyUSB0",
    "debug_flags": {
        "filename": "debug.txt",
        "level": 1
    },
    "last_updated": 1552207883,
    "report_server": "reports.hilster.io"
}
```

can easily be loaded with

```
s = htf.Settings(filename="settings.json")
print(s)
# <htf.Settings filename='settings.yml' data={
# "comport": "/dev/ttyUSB0",
# "debug_flags": {
#     "filename": "debug.txt",
#     "level": 1
# },
# "last_updated": 1552207883,
```

```
# "report_server": "reports.hilster.io"
# }>
```

To access members use

```
s.comport  # or
s["comport"]
```

To set a single member use

```
s.another_comport = "/dev/ttyUSB1"  # or
s["another_comport"] = "/dev/ttyUSB1"
```

To update the settings with another dictionary or other settings use

```
s.update(dict(a=1, b=2))
print(s)
# <htf.Settings filename='settings.json' data={
# "a": 1,
# "b": 2,
# "comport": "/dev/ttyUSB0",
# "debug_flags": {
#     "filename": "debug.txt",
#     "level": 1
# },
# "last_updated": 1552207883,
# "report_server": "reports.hilster.io"
# }>
```

To save settings use

```
s.save()
```

YAML Example

A YAML settings file named `settings.yml` and the contents

```
# This is a comment within a settings file that JSON does not support
comport: "/dev/ttyUSB0"
debug_flags:
    filename: "debug.txt"
    level: 1
last_updated: 1552207883
report_server: "reports.hilster.io"
```

can easily be loaded with

```
s = htf.Settings(filename="settings.yml")
print(s)
# <htf.Settings filename='settings.yml' data={
# "comport": "/dev/ttyUSB0",
# "debug_flags": {
#     "filename": "debug.txt",
#     "level": 1
# },
# "last_updated": 1552207883,
# "report_server": "reports.hilster.io"
# }>
```

Attention: when saving YAML all comments are lost!

Create a Settings File

To create new settings use

```
s = htf.Settings(
        filename="new_settings.yml",
        create="True",
        defaults={
            "foo": "bar",
        })
# save settings
s.save()
# cat new_settings.yml
# foo: "bar"
```

htf.Settings

```
class htf.Settings(*args: Any, **kwargs: Any)
```

`Settings` can be used to access local settings easily. It is a singleton.

The local settings file is automatically searched looking in `$HTF_SETTINGS`, `$HOME/settings.{txt,json,yml,yaml}` or `./settings.{txt,json,yml,yaml}` in this order. If no settings file was found an exception is raised except `create` is `True`.

Settings are stored in JSON or YAML format. If the file extension is `.yml` or `.yaml` YAML data is assumed else JSON.

Instantiate a Settings instance.

Parameters:

- **filename=None** – the filename to load explicitly

- **create=False** – if set to `True` no exception is raised if no settings are found to create new settings
- **defaults=None** – if set to a dict these values are used as default values before loading the settings file

```
get(key: str, default: Any | None = None) → Any
```

Get an item and return `default` if the item was not found.

Parameters:

- **key** – key for item
- **default=None** – is returned if `key` was not found.

Returns:
self[key]
Return type:
object

```
get_filename() → str | None
```

Return the currently used settings filename.

```
get_settings_filenames() → List[str]
```

Return a list of possible settings filenames that are tried in order. The first available file is used. You can overwrite this method in your specialized `Settings`.

Returns:
a list of filenames that are tried to be opened from left to right.
The first file that is opened will be used to read settings from.

Return type:
list

```
items() → Iterator[Any]
```

Iterate over items like in a dict.

Returns:
Iterator over the items (key, value)

```
save() → None
```

Save current settings to current filename (useful after modification).

Attention: YAML comments are lost when overwriting an existing YAML file!

```
update(data: Dict[str, Any]) → None
```

Update settings with `data`.

Parameters:
data – data to use for update

htf.SettingsNoSingleton

```
class htf.SettingsNoSingleton(*args: Any, **kwargs: Any)
```

Settings without being a singleton.

Instantiate a Settings instance.

Parameters:

- **filename=None** – the filename to load explicitly
- **create=False** – if set to `True` no exception is raised if no settings are found to create new settings
- **defaults=None** – if set to a dict these values are used as default values before loading the settings file

```
get(key: str, default: Any | None = None) → Any
```

Get an item and return `default` if the item was not found.

Parameters:

- **key** – key for item
- **default=None** – is returned if `key` was not found.

Returns:
self[key]
Return type:
object

```
get_filename() → str | None
```

Return the currently used settings filename.

```
get_settings_filenames() → List[str]
```

Return a list of possible settings filenames that are tried in order. The first available file is used. You can overwrite this method in your specialized `Settings`.

Returns:
a list of filenames that are tried to be opened from left to right.
The first file that is opened will be used to read settings from.

Return type:
list

```
items() → Iterator[Any]
```

Iterate over items like in a dict.

Returns:
Iterator over the items (key, value)

```
save() → None
```

Save current settings to current filename (useful after modification).

Attention: YAML comments are lost when overwriting an existing YAML file!

```
update(data: Dict[str, Any]) → None
```

Update settings with `data`.

Parameters:
data – data to use for update

Decorators

Decorators can be used to change the behaviour of a method by *decorating* it.

Decorators that are included in htf are:

htf.test

Decorate function or method to be interpreted as a test.

```
@htf.test
def function():
    pass
```

```
htf.test(func: Callable[[...], Any]) → Callable[[...], Any]
```

Mark a function or method as a test.

htf.after

Run additional commands after the test function.

```
def run_after(*args, **kwargs):
    print("run_after", args, kwargs)

@after(run_after, 1, 2, 3, a="b")
def function():
    print("function")
function()
# prints:
# function
# run_after (1, 2, 3) {'a': 'b'}
```

```
htf.after(after_function: Callable[[...], Any], *after_args: Any, **after_kwargs: Any) →
Callable[[Callable[[...], Any]], Any]
```

The *@after* decorator decorates a method so that *after_function* is called after the decorated function is called itself.

Parameters:

- **after_function** – the function to be run after the decorated function.
- ***after_args** – positional arguments to be passed to `afterFunction`.
- ****after_kwargs** – keyword-arguments to be passed to `afterFunction`.

htf.before

Run additional commands before the test function.

```
def run_before(*args, **kwargs):
    print("runBefore", args, kwargs)

@before(run_before, 1, 2, 3, a="b")
def function():
    print("function")
function()
# prints:
# run_before (1, 2, 3) {'a': 'b'}
# function
```

```
htf.before(before_function: Callable[[...], Any], *before_args: Any, **before_kwargs: Any) →
Callable[[Callable[[...], Any]], Any]
```

The *@before* decorator decorates a method so that *before_function* is called before the decorated function is called itself.

Parameters:

- **before_function** – the function to be run before the decorated function.
- ***before_args** – positional arguments to be passed to `beforeFunction`.
- ****before_kwargs** – keyword-arguments to be passed to `beforeFunction`.

htf.enqueue_exception

Decorate a method to fetch its exception that is enqueued into an exception queue.

```
@enqueue_exception(queue)
def decorated_method():
    raise Exception("This is a test")
```

```
htf.enqueue_exception(queue: Queue) → Callable[[Callable[[...], Any]], Any]
```

Decorate a method to fetch its exception that is enqueued into an exception queue. The enqueued exception can be handled elsewhere. The caught exception can be raised after enqueueing it.

Just decorate you method with the queue to be used and every exception that is raised within the decorated method will be put into the queue before the exception is raised again.

Parameters:
queue – the queue to enqueue the exception.

htf.metadata

Provides a way to set metadata in the test report for the decorated function.

```
@htf.metadata(name="Bob", age="20")
def test_with_metadata():
    pass
```

```
htf.metadata(**metadata: Any) → Callable[[...], Any]
```

Provides a way to set metadata in the test report for the decorated function.

Parameters:
metadata – the dictionary of metadata

htf.requirements

Used to show that a test checks a certain requirement.

```
@requirements("REQ_1", "REQ_2")
def test_with_requirements():
    pass
```

```
htf.requirements(*requirements: str) → Callable[[Callable[[...], Any]], Any]
```

The `@requirements` decorator reports which requirements are checked by a test in the test report shown in the `HTMLTestReport`.

Parameters:
***requirements** – a tuple of strings that name the checked requirements, eg. “REQ_1”, “REQ_2”, etc.

htf.implements

Used to annotate a test with implemented tests. These links are used to generate links in test reports and to send test results back to ALM/QMS systems.

```
@implements("TEST-1", "TEST-2")
def test_implementing_test_specifications():
    pass
```

```
htf.implements(*tests: str) → Callable[[Callable[[...], Any]], Any]
```

The `@implements` decorator reports which tests are implemented.

Parameters:
***tests** – A tuple of strings that name the implemented tests, eg. “TC-1”, “TC-2”, etc. You can also pass a url, eg. “http://server/path/to/testcase” where “testcase” is the id

htf.meets_doors_requirements

To use in conjunction with the `doors_testreport` to show that a test checks a certain requirement.

```
@meets_doors_requirements("doors://host:port/path-without-id-",
                  "REQ_1", "REQ_2")
def test_with_a_useful_name():
    pass
```

```
htf.meets_doors_requirements(base_url: str, *requirements: str) → Callable[[Callable[[...],
Any]], Any]
```

The `@meets_doors_requirements` decorator reports which requirements are checked by a test in the test report shown in the `doors_testreport` and the `HTMLTestReport`.

Parameters:

- **base_url** – the DOORS base url the links are created with.
- ***requirements** – a tuple of strings that name the checked requirements, eg. “REQ_1”, “REQ_2”, etc.

htf.periodic

Run a decorated function periodically.

```
@periodic(period=1.0)
def periodically_called_every_second():
    print("call")
```

`@periodic` can also be used within classes

```
class ClassWithAPeriodicMethod():

    @periodic(period=1.0)
    def periodically_called_every_second(self):
        print("call")
```

```
htf.periodic(period: float, maximum_period: float | None = None, run_condition:
Callable[[...], bool] | None = None, raise_exception: bool = True) →
Callable[[Callable[[...], Any]], Any]
```

Decorate a method to be run periodically.

Parameters:

- **period** – the period in seconds.
- **maximum_period=None** – if set to a float >= *period* the periodic method may take up to *maximum_period* time without raising an exception. A warning is printed on stdout instead.
- **run_condition=None** – a callable (method or lambda expression) that has to return true while the method is run periodically.
- **raise_exception=True** – if set to `True` an exception is raised if the called method takes longer than the period (or `maximum_period` if set).

Warning

Non-realtime operating systems will not ensure timing accuracy.

htf.raises

The decorated function will catch an exception

```
@raises(AssertionError)
def test_failure(assertions):
```

```
    assertions.assert_true(False)

@raises(TimeoutException, UnknownException)
def test_exceptions():
    raise TimeoutException("timeout")
    raise UnknownException("unknown exception")
```

```
htf.raises(*exceptions: BaseException) → Callable[[Callable[[...], Any]], Any]
```

Decorate a method to catch different exceptions.

Parameters:
***exceptions** – a tuple of exceptions that are fetched.

htf.skip

Decorate to skip the test method or function.

```
@skip("This test is skipped in view of the occasion")
def test_always_skipped():
    pass
```

```
htf.skip(reason: str) → Callable[[Callable[[...], Any]], Any]
```

Decorate a method to be skipped in view of the occasion.

Parameters:
reason – the reason to be put into the test report.
Raises:
SkipTest – to skip the test.

htf.skip_if

Decorate to skip test if condition evaluates to `True` at runtime. Condition is called with the same parameters like the decorated test including all fixtures, etc. and if it failes it is called without parameters.

```
def skip_tests():
    return True

@htf.skip_if(skip_tests, "Skipped if skip_tests returns True")
def test_skipped_if():
    pass

@htf.skip_if(True, "Always skipped")
def test_always_skipped():
    pass
```

```
@htf.skip_if(False, "Never skipped")
def test_never_skipped():
    pass

@htf.skip_if(lambda: True, "Always skipped")
def test_always_skipped_lambda():
    pass

def condition():
    return True

@htf.skip_if(condition, "skipped")
def test_always_skipped_with_bound_method(self):
    pass

class SkipTests(htf.TestCase):
    def condition(self, *args, **kwargs):
        # can only be evaluated at runtime
        return True

@htf.skip_if(condition, "classed skipped")
def test_skipped_by_instance_condition(self, assertions):
    pass

def ddt_condition(a):
    return a < 100

@htf.data(range(3))
@htf.skip_if(ddt_condition, "skipped ddt")
def test_ddt_skipped(a):
    pass

def fixture_condition(assertions):
    return True

@htf.skip_if(fixture_condition, "skipped with fixtures")
def test_skipped_with_fixtures(assertions):
    pass

def catch_all_condition(*args, **kwargs):
    return True

@htf.skip_if(catch_all_condition, "skipped with args and kwargs")
def test_args_kwargs(assertions, delay, step):
    pass
```

```
htf.skip_if(condition: bool | Callable[[...], bool], reason: str) →
Callable[[Callable[[...], Any]], Any]
```

Decorate a method to be skipped. The `condition` is evaluated at runtime. Note that `condition` is evaluated twice by the test runner and the test itself. Thus, it should not introduce any side effects.

Parameters:

- **condition** – the condition may be `True`, `False` or a callable object that must return `True` or `False`. The decorated test is skipped if `condition` is `True` or returns `True`.
- **reason** – the reason to be put into the test report.

Raises:
SkipTest – to skip the test if `condition` is or returns `True`.

htf.stacktrace

Every time the decorated function is called, the call stack will be printed.

```
@stacktrace
def function():
    pass

function()  # will print(the call stack to stdout)
```

```
htf.stacktrace(func: Callable[[...], Any]) → Callable[[...], Any]
```

The `@stacktrace` decorator decorates a method so that its call stack is printed to stdout every time it is called. This is useful for debugging.

htf.tags

Attach a tag to tests, fixtures or classes.

```
htf.tags(*tags: str) → Callable[[Callable[[...], Any]], Any]
```

Tag a test or class.

Parameters:
***tags** – the tags to be used

htf.timed

Ensure ending of a method or function within a given time limit.

```
@timed(limit=0.1)
def decorated_method_that_fails():
    time.sleep(0.2)

@timed(limit=1.0)
def decorated_method_that_does_not_fail():
    time.sleep(0.2)
```

```
htf.timed(limit: float) → Callable[[Callable[[...], Any]], Any]
```

Decorate a method to ensure that it ends within a given time limit.

Parameters:
limit – the time limit in seconds.

User-Defined Decorators

Users can add their own decorators for their own code.

Since htf supports coroutines, functions and methods as tests, user-defined decorators need to support those as well.

Note that some decorators deliver a coroutine regardless of the decorated object.

Therefore, the decorator needs to check whether the decorated object is a coroutine or not and call it accordingly.

```
import asyncio
from functools import wraps

def user_decorator() -> Callable[[Callable[..., Any]], Any]:
    def wrapper(func: Callable[..., Any]) -> Callable[..., Any]:
        @wraps(func)
        async def _user_decorator_wrapper(*args: Any, **kwargs: Any) -> Any:
            # user code
            if asyncio.iscoroutinefunction(func):
                await func(*args, **kwargs)  # call a coroutine
            else:
                func(*args, **kwargs)  # call everything that is not a coroutine
            # user code
        return _user_decorator_wrapper
    return wrapper

@user_decorator()
@htf.requirements("REQ-1")
def test_example():
    pass

@user_decorator()
@htf.requirements("REQ-1")
async def test_example_async():
    pass
```

Test Reports

HILSTER Testing Framework includes test reports for HTML, XML, YAML and JSON.

HTML Test Report

The HTML test report is a monolithic Javascript application that does not need to load any external data.

Historical HTML test-report walkthrough

Download recording · Download transcript

```
Historical HTML test-report walkthrough
=======================================

Visual walkthrough of the silent original screen recording, based on reviewed
overview/detail/filter/search/attachment/print frames. This records the historical
interface, not a newly executed test run or current product validation.

Original recording: showcase_testreport.mp4

1. Open the report overview. A doughnut chart and result bar summarize six tests:
   three successful tests, one failure, one error, and one skipped test. Hovering
   the chart highlights the successful half and displays its count/percentage.

2. Open an error result. The expanded red result card displays an exception,
   traceback, timestamps/duration, documentation, metadata and captured stdout.

3. Browse the All and Success result lists from the sidebar. The All list contains
   docstring, error, failure, plot/attachment, skip and CAPTCHA examples; Success
   narrows the list to the three successful tests.

4. Use the search box to filter for attach. Matching text is highlighted in the
   plot/attachments result. Its expanded green card shows the documentation, tags,
   successful Create plot/Attach plot steps, metadata, stdout and a Lorenz Attractor
   image attachment. Clear the search to return to the result list.

5. Open the printable report and scroll through it. The print view contains the
   HILSTER title page, overview and individual test details, including the docstring
   example with table/text content and the error example with its traceback.
```

When loading the test report, a progress bar appears, and the percentage of loaded tests is shown. The HTML test report usually loads very fast.

When the test report has finished loading, a responsive interface is shown, allowing you to interact with the test report.

Navigation

The navigation is located in the sidebar to the left. The first two entries, `Overview` and `Metadata`, are helpful for getting an initial impression of the test run. When the test report is loaded, `Overview` is shown by default, visualizing and summarizing the test results in an easy to understand way. `Metadata` shows test run specific information.

The remaining entries are used for navigating through the test results, and filtering which test results to display. Clicking `All` shows all test results. When selecting result types (`Success`, `Error`, `Failure` and `Skipped`), the test results get filtered accordingly. It is possible to select multiple result types at once. The number of tests within the respective result types are shown next to the filters.

Note that clicking `All`/pressing `esc` resets any applied filters.

Information about the host, the platform the tests were run on and licensing information are shown at the bottom of the sidebar on the left.

The sidebar can be hidden by clicking on the hamburger icon on the top, next to the logo.

Test title and test date are shown in the top right corner.

Overview

The visualisation is hierarchical: The inner ring represents the the four results types `success`, `error`, `failure` and `skipped`, as shown in the sidebar. The next ring shows more detailed information, such as exception types for failures and errors, and skip reasons for skipped tests. These information get even more detailed in the outer ring, making it possible to easily identify concrete exception strings within respective exception types.

Hovering over the diagram reveals additional information, such as hierarchy paths and statistics.

Clicking a section of the diagram searches the test report for the respective result type/exception type/exception string.

Test results

The main content is located to the right of the sidebar, containing all test results. Clicking on a result expands the respective test and shows further information. By default all test results are collapsed.

Every test result contains different test properties, such as `result`, `traceback`, `metadata`, `documentation`, `tags`, `dates`, `attachments`, captured `stdout` and captured `stderr`. To improve performance, long output (`stdout` and `stderr`) is not loaded by default. Clicking on `show more` loads the respective output.

File attachments

The HTML test report supports file attachments that you can attach to a test using `htf.TestCase.attach_file` (or `htf.TestCase.attachFile`).

File attachments are not supported by all browsers. For more information see Browser Limitations.

URL attachments

You can also attach URLs by using `htf.TestCase.attach_url` (or `htf.TestCase.attachUrl`) in your test.

Searching

Clicking on the magnifier icon on the top opens a search interface. The HTML test report offers three different search methods: Default search, global search and special pattern search.

Note that only selected categories get searched. In order to search all testresults, you would need to select `All` in the sidebar.

The search interface can be closed by clicking on the small `x` to the right of the search bar.

Default search

By default, only test titles get searched. Typing in the search bar instantly triggers the search.

Toggling the regex slider, located to the right side of the search bar, allows the user to perform a search using regular expressions.

The test report also offers two additional advanced searching methods, global search and special pattern search.

Global search

Global search requires the search term to be prefixed with `global:`, and allows the user to search not only titles, but also in any test properties within the test results, such as `Dates`, `Traceback` or `Tags`.

For example to search for tests that include `foo`, the user would use `global:foo`.

To search for tests that include `foo` or `bar`, you would use `global:foo|bar`, combining global search with regular expressions.

Special pattern search

Special pattern search allows to search in specific test properties, such as `Tags`, `Dates` or `Traceback`, by using the name of the respective property as prefix in lowercase. For example, to search for tests tagged with `tag_1`, one would search for `tags:tag_1`. Accordingly, searching for tests which were started on `2020-01-09`, one would search for `dates:2020-01-09`.

This can also be used to filter for all tests containing a specific property. For example, to only show tests containing `Tags`, one would search for `tags:`.

Goto

When pressing `g`, an input field appears next to the search bar, allowing the user to jump to a specific test. Entering the test run number (which can be shown by pressing `n`) of the respective test and pressing `Enter` expands and focuses the test.

Bookmarking

Right-clicking a test bookmarks the test for easier access. A bookmark-section is shown in the sidebar when there are active bookmarks.

Draft

Even when not all tests are run yet, the test report can be interacted with. This is indicated by a red `draft` sign in the sidebar.

Printing

While in test run overview, a print icon is shown in the upper right corner. Clicking it will render a print optimized version of the test report, including an overview diagram, the test run metadata and a signature page.

In print view, every test will get expanded and printed on a dedicated page for easier readability.

Dark Mode

For easier readability, the testreport color scheme can be changed to a darker variant by pressing `D`. Pressing the hotkey again switches back to the light theme.

Hotkeys

The HTML test report supports the following hotkeys:

Key	Description
`h`	Show help (any click or key but `h` hides it again)
`esc`	Reset view: hide help, hide search box, show all results
`a`	Collapse all expanded test results
`o`	Show test run overview diagram
`m`	Show test run metadata
`a`	Show all results
`s`	Toggle successes
`f`	Toggle failures
`e`	Toggle errors
`S`	Toggle skipped
`F`	Show search interface
`R`	Show search interface and toggle regex parameter
`g`	Show goto interface to jump to a specific test
`n`	Toggle test run numbers
`b`	Toggle sidebar
`l`	Show open source licenses
`p`	Show printable version of test report
`D`	Activate Dark Mode

The only hotkey you have to remember is `h` though.

Browser Limitations

Most modern browsers, such as Firefox, Chrome and Microsoft Edge (Version 80+), support the whole functionality of the test report.

File attachments are realized using data-urls.

Some Microsoft-browsers do not support them at all. Chrome and Chromium have security features in place, but support an acceptable workaround.

The following browser limitations are known:

Browser	Limitations
`IE 11 and older`	• Not officially supported.
`Edge (Version 78 and earlier)`	• Only image attachments can be downloaded by right clicking and choosing `save image as`. Downloading other types of attachments is not possible, since older versions of Edge do not fully support downloading data-urls. Everything else works well.
`Chrome/Chromium/` `Edge (Version 80+)`	• Attachments cannot be viewed or downloaded with a single click on it. As a workaround you can use the context menu and use `save as` or `open in another tab`.

Your browser must have Javascript enabled to view the test report. There are some plugins like `NoScript` that will likely cause problems. Also old versions of Internet Explorer do not load Javascript by default.

JUnit XML Test Report

HILSTER Testing Framework creates JUnit XML test reports that can be used in other tools like Continuous Integration systems, etc.

The JUnit XML format does not include all available data htf offers.

JSON Test Report

The JSON test report includes all test results with all data to be used in your tools.

YAML Test Report

The YAML test report includes all test results with all data to be used in your tools.

IBM® Engineering Requirements Management DOORS Test Report

The IBM® Engineering Requirements Management DOORS Test Report is a special test report that creates a DXL script to be imported into DOORS. Thus your test results can easily be imported to DOORS.

The DOORS Test Report works in conjunction with the `@meets_doors_requirements` decorator that attaches the tested requirements to individual tests.

```
@meets_doors_requirements("doors://host:port/path-without-id-",
                  "REQ_1", "REQ_2")
def test_with_useful_name():
    pass
```

The IBM Rational DOORS Test Report can only be used within Python code because it needs configuration parameters.

```
import htf

@htf.meets_doors_requirements("REQ_1", "REQ_2", "REQ_3", "TEST_1")
def test_with_doors_links():
    pass

htf.main(title="DOORS Test Report",
    extra_report=[
             DOORSTestReport(filename="doors.dxl",
                             report_module="/path/to/report/module",
                             requirements_modules={
                                 "REQ_.*" : "/path/to/requirements_module",
                                 "TEST_.*" : "/path/to/test_specification",
                             },
                             links_modules={
                                 "REQ_.*" : "/path/to/links/to/requirements_module",
                                 "TEST_.*" : "/path/to/links/to/test_specification",
                                 }
                             )
             ],
    )
```

```
class htf.DOORSTestReport(filename: str, report_module: str, requirements_modules: Dict[str,
str], links_modules: Dict[str, str] | None = None, render_meta_data: bool = True,
render_steps: bool = True)
```

`DOORSTestReport` creates a DOORS test report. Links are automatically created from the created DOORS module to the fulfilled requirements.

To state the fulfilled requirements the `meets_doors_requirements` decorator should be used.

Initialize a `DOORSTestReport` instance.

Parameters:

- **filename** – the filename for the DXL test report.
- **report_module** – the DOORS path to the report module.
- **requirements_modules** – maps links to DOORS modules. The keys are regular expressions and the values are the desired target modules.
- **links_modules={".*"** – “DOORS Links”}: maps requirements to desired link modules. The keys are regular expressions and the values are the desired link modules.
- **render_meta_data=True** – if set to *True* metadata is rendered in DOORS

- **render_steps=True** – if set to *True* steps are rendered in DOORS

```
render(data: Dict[str, Any]) → None
```

Generates and stores a DXL encoded TestReport.

Parameters:
data – test result data

Signed Reports

The HILSTER Testing Framework supports signed test reports since version `htf-1.2`.

Signed reports are a very useful feature to proof that a test report was not modified.

This could be useful when dealing with certification authorities or during legal proceedings to document when, how and to what degree a product was tested.

The signature is created using asymmetric cryptography. This allows for independent verification of the signatures validity with the public key.

Signed reports can be verified by others using the `checksignatures` command line utility which does not need to be licensed and which is shipped with `htf`.

Creating signed reports

Signed reports can only be created for the internal reports of the HILSTER Testing Framework. These are the HTML-report, the JUnit-xml-report and the JSON-Report. User supplied reports are not signed for security reasons.

To be able to create signed reports you need to license the `htf.signatures` feature. Once the feature is enabled `htf.signatures` signed reports are created automatically if you use `$ htf`, `$ htf run`, `$ htf dryrun`, `htf.main`, `htf.run` or `htf.dryrun`.

The signature is written into an extra file with the name of the report plus `.sig`.

To disable the creation of signatures you can set the environment variable `HTF_SIGN_REPORTS` to `"0"` using `set HTF_SIGN_REPORTS=0` on Windows or `export HTF_SIGN_REPORTS=0` on Linux.

Checking signatures

`checksignatures` is free to use and does not need a license.

To check signatures you can use the `checksignatures` commandline utility which is shipped with `htf`.

When called without any parameters `checksignatures` scans the current folder and prints the status of the files found.

Files without signatures can be omitted by using the `-s` option.

To verify specific files or folders, add them as parameters seperated by whitespace.

Report Tool

`report-tool` is a command line utility to convert reports into different formats, merge reports from different formats into different formats and extract attachments, stdout and stderr from reports to reduce their size.

Supported input formats are HTML, JUnit-XML, JSON and YAML.

Supported output formats are also HTML, JUnit-XML, JSON, YAML. Reports can also be uploaded to a Dashboard.

Usage

The usage is simple. To see all options run `report-tool -h`.

```
usage: report-tool [-h] [-t TITLE] [-H HTML_REPORT] [-x JUNIT_XML_REPORT] [-j JSON_REPORT] [-Y
YAML_REPORT] [-r REPORT_SERVER]
               [--extract-output] [--extract-attachments]
               report [report ...]

report-tool - HILSTER Testing Framework (HILSTER GmbH, https://hilster.io)

positional arguments:
  report                The input test report. All formats are supported. (may be repeated)

optional arguments:
  -h, --help            show this help message and exit
  -t TITLE, --title TITLE
                        Output testreport title
  -H HTML_REPORT, --html-report HTML_REPORT
                        Output HTML report filename (may be repeated)
  -x JUNIT_XML_REPORT, --junit-xml-report JUNIT_XML_REPORT
                        Output Junit-compatible XML report filename (may be repeated)
  -j JSON_REPORT, --json-report JSON_REPORT
                        Output JSON report filename (may be repeated)
  -Y YAML_REPORT, --yaml-report YAML_REPORT
                        Output YAML report filename (may be repeated)
  -r REPORT_SERVER, --report-server REPORT_SERVER
                        URL to report server (may be repeated)
  --extract-output
                        Extract STDOUT and STDERR from each test and store it into a text file.
  --extract-attachments
                        Extract attachments and store them locally.
```

Convert Reports

To convert a report into a different format add the source and add the outputs you want to create.

For example to create a JUnit-XML report from an HTML report run:

```
report-tool testreport.html --junit-xml-report testreport.xml
```

And to create all possible file formats run

```
report-tool testreport.html -x testreport.xml -H new_testreport.html -j testreport.json -Y
testreport.yml
```

Merge Reports

To merge reports add more than one source. All sources are combined automatically. The resulting start time is the minimum start time of all supplied sources. The resulting stop time is the maximum stop time of all supplied sources.

All test report metadata are put into every single test metadata with a prefix `'original'` and the test run metadata is replaced with the sources of the merge and the `report-tool` command used.

For example to create an HTML report from an HTML report and a JUnit-XML report run:

```
report-tool testreport.html results.xml -H merged.html
```

Upload Reports

To upload a report to your Dashboard use `-r` or `--report-server` with the url to your Dashboard and project.

In the following example `testreport.html` is uploaded to your Dashboard to project `example-project`.

```
report-tool testreport.html --report-server https://dashboard.lan/example-project
```

Of course you can also merge and upload reports with a single command. To merge `testreport.html` and `results.xml` and upload it run:

```
report-tool testreport.html results.xml --report-server https://dashboard.lan/example-project
```

Set the Report Title

To set the report title use `-t` or `--title`.

```
report-tool testreport.html --title "New Test Report" -H new_testreport.html
```

Signed Reports

If all input reports have a valid signature and the `signature` feature is enabled in your license a signature for the output will be created, too.

Extract Attachments

If your HTML report (or another report) contains attachments and is very big so your browser cannot open it anymore you can extract the attachments and write a new report without attachments. The extracted attachments are stored to disk with a reasonable filename and thus can be viewed easily.

To extract attachments from `testreport.html` and create `stripped.html` run:

```
report-tool testreport.html --extract-attachments --html-report stripped.html
```

Extract Output

If your HTML report (or another report) contains stdout and stderr and is very big so your browser cannot open it anymore you can extract stdout and stderr and write a new report without output. The extracted outputs are stored to disk with a reasonable filename and thus can be viewed easily.

To extract attachments from `testreport.html` and create `stripped.html` run:

```
report-tool testreport.html --extract-output --html-report stripped.html
```

Community Add-ons

The HILSTER Testing Framework community offers community add-ons in an external GitHub repository.

Modbus — The Modbus Testing Framework

`htf` includes a full-stack Modbus implementation since version 1.3 with the following features:

- Serial RTU, Serial ASCII, TCP, TLS and UDP support
- client support
- device simulator support
- default Modbus protocol
- extended Modbus protocol
- supported endianness: little endian, big endian, word aligned and half-word aligned
- protocol abstraction is based on `oser`
- working with data `oser` structures instead of bits and bytes
- fault insertion

• possibility to extend client and device simulator with own commands

The Modbus implementation is capable of testing Modbus clients and servers.

Examples

Simulating a Modbus-Device

```
import htf
from htf.modbus import ModbusTCPDevice, ModbusTCPClient

ADDRESS = 'localhost'
PORT = 10502  # must be able to run for non-root users

@htf.fixture(scope='class', name='device')
def create_device_simulator():
    device = ModbusTCPDevice(ADDRESS, port=PORT)
    yield device
    device.close()

@htf.fixture(scope='test', name='client')
def create_client():
    client = ModbusTCPClient(ADDRESS,
                             port=PORT,
                             references_start_at_one=False,
                             auto_disconnect=False,
                             debuglevel=0)  # set debuglevel to 1 or 2
    yield client
    client.close()

class ModbusTCPTests:
    """
    This tests shows how to simulate a modbus device and how to use the client to
    query it via TCP/IP.
    """

    def test_holding_registers(self, device, client, assertions):
        registers = client.read_multiple_holding_registers(0, 8)
        assertions.assert_equal(registers, [0] * 8)

        for address in range(10):
            client.write_multiple_holding_registers(address, [0, 1, 0, 1, 1, 0, 1, 0])
            registers = client.read_multiple_holding_registers(address, 8)
            assertions.assert_equal(registers, [0, 1, 0, 1, 1, 0, 1, 0])

            device.write_multiple_holding_registers(address, [1, 1, 0, 0, 1, 0, 1, 0])
            registers = client.read_multiple_holding_registers(address, 8)
            assertions.assert_equal(registers, [1, 1, 0, 0, 1, 0, 1, 0])

    def test_input_registers(self, device, client, assertions):
        device.write_multiple_input_registers(0, list(range(10)))

        registers = client.read_multiple_input_registers(0, 10)
```

```
        assertions.assert_equal(registers, list(range(10)))

        registers = device.read_multiple_input_registers(0, 10)
        assertions.assert_equal(registers, list(range(10)))

        device.write_multiple_input_registers(10, list(range(20, 31)))

        registers = client.read_multiple_input_registers(5, 15)
        assertions.assert_equal(registers, list(range(5, 10)) + list(range(20, 30)))

        for i in range(10):
            r = client.read_input_register(i)
            assertions.assert_equal(r, i)

            r = device.read_input_register(i)
            assertions.assert_equal(r, i)

        for i in range(10, 20):
            r = client.read_input_register(i)
            assertions.assert_equal(r, i+10)

            r = device.read_input_register(i)
            assertions.assert_equal(r, i + 10)

        device.write_input_register(2323, 1)
        r = client.read_input_register(2323)
        assertions.assert_equal(r, 1)

if __name__ == '__main__':
    htf.main()
```

Special Modbus Data Structures

```
import htf
import oser
from datetime import datetime
from htf.modbus import ModbusTCPDevice, ModbusTCPClient

ADDRESS = 'localhost'
PORT = 10502  # must be able to run for non-root users

class DateTime(oser.ByteStruct):
    def __init__(self, value=None):
        """
        ``DateTime`` data type.

        Args:
            value (datetime): a datetime instance to be used
        """
        super(DateTime, self).__init__()

        self.year = oser.UBInt16()
        self.month = oser.UBInt8()
        self.day = oser.UBInt8()
```

```
        self.hour = oser.UBInt8()
        self.minute = oser.UBInt8()
        self.second = oser.UBInt8()

        if value is not None:
            self.set(value)

    def set(self, value):
        """
        Set values from a ``datetime`` instance.

        Args:
            value (datetime): a ``datetime`` instance to be used
        """
        if not isinstance(value, datetime):
            raise ValueError("value must be of type datetime")

        self.year.set(value.year)
        self.month.set(value.month)
        self.day.set(value.day)

        self.hour.set(value.hour)
        self.minute.set(value.minute)
        self.second.set(value.second)

    def get(self):
        """
        Get values as datetime.

        Returns:
            datetime: an instance of ``datetime`` containing the current values
        """
        return datetime(year=self.year.get(), month=self.month.get(), day=self.day.get(),
                        hour=self.hour.get(), minute=self.minute.get(), second=self.second.get())

@htf.fixture(scope='class', name='device')
def create_device_simulator():
    device = ModbusTCPDevice(ADDRESS, port=PORT)
    yield device
    device.close()

@htf.fixture(scope='test', name='client')
def create_client():
    client = ModbusTCPClient(ADDRESS,
                             port=PORT,
                             references_start_at_one=False,
                             auto_disconnect=False,
                             debuglevel=0)  # set debuglevel to 1 or 2
    yield client

        device.write_input_register_data(23, DateTime(now))

        current_date_struct = client.read_input_register_data(23, DateTime)

        assertions.assert_equal(current_date_struct.year, now.year)
        assertions.assert_equal(current_date_struct.month, now.month)
        assertions.assert_equal(current_date_struct.day, now.day)

        assertions.assert_equal(current_date_struct.hour, now.hour)
        assertions.assert_equal(current_date_struct.minute, now.minute)
        assertions.assert_equal(current_date_struct.second, now.second)

        print("device date time is:", current_date_struct.get())

if __name__ == '__main__':
    htf.main()
```

Interfaces

Interfaces are used to implement communication. The user may add other interfaces if needed.

Serial RTU Client Interface

```
class htf.modbus.ModbusSerialRTUClientInterface(com_port: str | None = None, baud: int =
9600, bytesize: int = 8, parity: str = 'E', stopbits: int = 1, rtscts: bool = False, timeout:
int | float = 1.0, response_parser: ByteStruct | BitStruct | ByteType | BitType = <class
'htf.modbus.protocol.SerialRTUModbusResponse'>)
```

Parameters:

- **com_port** – the com port to be used
- **baud** – the baud rate
- **bytesize** – number of bits in a byte
- **parity** – serial.PARITY_NONE, serial.PARITY_ODD or serial.PARITY_EVEN
- **stopbits** – number of stopbits (1, 1.5 or 2)
- **rtscts** – if True use flow control
- **timeout** – the timeout in seconds
- **response_parser** – the parser to parse responses

```
close() → None
```

Close serial port.

```
read() → Tuple[bytes, None]
```

Read Modbus serial RTU responses from server.

Returns:
a tuple containing buffer, `None`

```
write(adu: SerialRTUModbusRequest) → None
```

Write `adu`.

Parameters:
adu – serializable RTU adu

Serial RTU Server Interface

```
class htf.modbus.ModbusSerialRTUServerInterface(com_port: str | None = None, baud: int =
9600, bytesize: int = 8, parity: str = 'E', stopbits: int = 1, rtscts: bool = False, timeout:
int | float = 1.0, response_parser: ByteStruct | BitStruct | ByteType | BitType = <class
'htf.modbus.protocol.SerialRTUModbusRequest'>)
```

Parameters:

- **com_port** – the com port to be used
- **baud** – the baud rate
- **bytesize** – number of bits in a byte
- **parity** – serial.PARITY_NONE, serial.PARITY_ODD or serial.PARITY_EVEN
- **stopbits** – number of stopbits (1, 1.5 or 2)
- **rtscts** – if True use flow control
- **timeout** – the timeout in seconds
- **response_parser** – the parser to parse responses

```
close() → None
```

Close serial port.

```
read() → Tuple[bytes, None]
```

Read Modbus serial RTU requests from client.

Returns:
a tuple containing buffer, `None`

```
write(adu: SerialRTUModbusRequest) → None
```

Write `adu`.

Parameters:
adu – serializable RTU adu

Serial ASCII Client Interface

```
class htf.modbus.ModbusSerialASCIIClientInterface(com_port: str | None = None, baud: int = 9600, bytesize: int = 8, parity: str = 'E', stopbits: int = 1, rtscts: bool = False, timeout: int | float = 1.0, response_parser: ByteStruct | BitStruct | ByteType | BitType = <class 'htf.modbus.protocol.SerialASCIIModbusResponse'>)
```

Parameters:

- **com_port** – the com port to be used
- **baud** – the baud rate
- **bytesize** – number of bits in a byte
- **parity** – serial.PARITY_NONE, serial.PARITY_ODD or serial.PARITY_EVEN
- **stopbits** – number of stopbits (1, 1.5 or 2)
- **rtscts** – if True use flow control
- **timeout** – the timeout in seconds
- **response_parser** – the parser to parse responses

```
change_ascii_delimiter(delimiter: bytes) → None
```

Change LF character to `delimiter`.

Parameters:
delimiter – bytes of length 1 containing the new ASCII delimiter

```
close() → None
```

Close serial port.

```
read() → Tuple[bytes, None]
```

Read Modbus serial ASCII responses from server. Read until line feed character.

Returns:
a tuple containing buffer, `None`

```
write(adu: SerialASCIIModbusRequest) → None
```

Write `adu`.

Parameters:
adu – serializable RTU adu

Serial ASCII Server Interface

```
class htf.modbus.ModbusSerialASCIIServerInterface(com_port: str | None = None, baud: int = 9600, bytesize: int = 8, parity: str = 'E', stopbits: int = 1, rtscts: bool = False, timeout: int | float = 1.0, response_parser: ByteStruct | BitStruct | ByteType | BitType = <class 'htf.modbus.protocol.SerialASCIIModbusRequest'>)
```

Parameters:

- **com_port** – the com port to be used
- **baud** – the baud rate
- **bytesize** – number of bits in a byte
- **parity** – serial.PARITY_NONE, serial.PARITY_ODD or serial.PARITY_EVEN
- **stopbits** – number of stopbits (1, 1.5 or 2)
- **rtscts** – if True use flow control
- **timeout** – the timeout in seconds
- **response_parser** – the parser to parse responses

```
change_ascii_delimiter(delimiter: bytes) → None
```

Change LF character to `delimiter`.

Parameters:
delimiter – bytes of length 1 containing the new ASCII delimiter

```
close() → None
```

Close serial port.

```
read() → Tuple[bytes, None]
```

Read serial ASCII Modbus requests from client.

Returns:
a tuple containing buffer, `None`

```
write(adu: SerialASCIIModbusRequest) → None
```

Write `adu`.

Parameters:
adu – serializable RTU adu

TCP Client Interface

```
class htf.modbus.ModbusTCPClientInterface(address: str, port: int = 502, timeout: int | float = 1.0, connect: bool = True)
```

Parameters:

- **address** – the ip-address to connect to
- **port** – the port
- **timeout** – the timeout in seconds
- **connect** – if set to `True` the socket connects automatically

```
close() → None
```

Close TCP connection.

```
open() → None
```

Open a socket.

```
read() → Tuple[bytes | None, None]
```

Read a TCP request from TCP server.

Returns:
a tuple containing buffer, `None`

```
reconnect() → None
```

Close socket and create a new one.

```
write(adu: TCPModbusRequest) → None
```

Write `adu`.

Parameters:

adu – serializable TCP adu

TCP Server Interface

```
class htf.modbus.ModbusTCPServerInterface(address: str, port: int = 502, timeout: int |
float = 1.0)
```

Parameters:

- **address** – the ip-address to listen on
- **port** – the port to listen on
- **timeout** – the timeout in seconds

```
accept() → Tuple[socket, Any]
```

Accept a new connection.

Returns:
a tuple containing connection, address

```
close() → None
```

Close TCP socket.

```
close_connection(connection: socket) → None
```

Close TCP connection.

```
read(connection: socket) → bytes
```

Read a TCP request from TLS client.

Returns:
a tuple containing buffer, `None`

```
write(connection: socket, adu: TCPModbusRequest) → None
```

Write `adu`.

Parameters:
adu – serializable TCP adu

UDP Client Interface

```
class htf.modbus.ModbusUDPClientInterface(address: str, port: int = 502, timeout: int |
float = 1.0)
```

Parameters:

- **address** – the ip-address to connect to
- **port** – the port
- **timeout** – the timeout in seconds

```
close() → None
```

Close TCP connection.

```
open() → None
```

Open a socket.

```
read() → Tuple[bytes | None, None]
```

Read a TLS request from TLS server.

Returns:
a tuple containing buffer, `None`

```
reconnect() → None
```

Close socket and create a new one.

```
write(adu: TCPModbusRequest) → None
```

Write `adu`.

Parameters:
adu – serializable TCP adu

UDP Server Interface

```
class htf.modbus.ModbusUDPServerInterface(address: str, port: int = 502, timeout:
Tuple[int, float] | None = None)
```

Parameters:

- **address** – the ip-address to listen on
- **port** – the port to listen on
- **timeout=None** – the timeout in seconds

```
close() → None
```

Close UDP socket.

```
read(bufsize: int = 300) → Tuple[bytes, Any]
```

Read a request from an UDP client.

Parameters:
bufsize – buffer size
Returns:
the received request

```
write(address: str, adu: TCPModbusRequest) → None
```

Write `adu`.

Parameters:

- **address** – the target ip-address
- **adu** – serializable TCP adu

TLS Client Interface

```
class htf.modbus.ModbusTLSClientInterface(address: str, port: int = 502, timeout: int |
float = 1.0, verify: bool = True, connect: bool = True, cafile: str | None = None, capath:
str | None = None, cadata: str | None = None)
```

Parameters:

- **address** – the ip-address to connect to
- **port** – the port
- **timeout** – the timeout in seconds
- **verify** – set to `False` to disable TLS certificate verification
- **connect** – if set to `True` the socket connects automatically
- **cafile** – path to a file of concatenated CA certificates in PEM format
- **capath** – path to a directory containing several CA certificates in PEM format
- **cadata** – either an ASCII string of one or more PEM-encoded certificates or a bytes-like object of DER-encoded certificates

```
close() → None
```

Close TCP connection.

```
open() → None
```

Open a socket.

```
read() → Tuple[bytes | None, None]
```

Read a TCP request from TCP server.

Returns:
a tuple containing buffer, `None`

```
reconnect() → None
```

Close socket and create a new one.

```
write(adu: TCPModbusRequest) → None
```

Write `adu`.

Parameters:
adu – serializable TCP adu

TLS Server Interface

```
class htf.modbus.ModbusTLSServerInterface(address: str, port: int = 502, timeout: int |
float = 1.0, certfile: str | None = None, keyfile: str | None = None, password: str | None =
None)
```

Parameters:

- **address** – the ip-address to listen on
- **port** – the port to listen on
- **timeout** – the timeout in seconds
- **certfile** – path to TLS certificate
- **keyfile** – path to TLS keyfile
- **password** – TLS password

```
accept() → Tuple[socket, Any]
```

Accept a new connection.

Returns:
a tuple containing connection, address

```
close() → None
```

Close TLS socket.

```
close_connection(connection: socket) → None
```

Close TCP connection.

```
read(connection: socket) → bytes
```

Read a TCP request from TLS client.

Returns:
a tuple containing buffer, `None`

```
write(connection: socket, adu: TCPModbusRequest) → None
```

Write `adu`.

Parameters:
adu – serializable TCP adu

Clients

Clients are used to query Modbus devices. Users can add own clients using own interfaces.

Base Client

```
class htf.modbus.ModbusBaseClient(interface: ModbusBaseInterface, request_parser:
Type[SerialRTUModbusRequest] | Type[SerialASCIIModbusRequest] | Type[TCPModbusRequest],
response_parser: Type[SerialRTUModbusResponse] | Type[SerialASCIIModbusResponse] |
Type[TCPModbusResponse], retries: int | None = None, references_start_at_one: bool = True,
debuglevel: int | None = None)
```

Parameters:

- **interface** – an interface to be used for communication
- **request_parser** – a parser for requests
- **response_parser** – a parser for responses
- **retries=None** – the number of retries until an exception is raised

- **references_start_at_one=True** – if set to `True` all references start at `1` else `0`
- **debuglevel** – the debuglevel (`None` disables debug, `1` prints requests and responses and `2` prints introspection)

```
build_request() → SerialRTUModbusRequest | SerialASCIIModbusRequest | TCPModbusRequest
```

Build and return an instance of the desired request parser.

Returns:
request parser

```
build_response() → SerialRTUModbusResponse | SerialASCIIModbusResponse |
TCPModbusResponse
```

Build and return an instance of the desired response parser.

Returns:
response parser

```
close() → None
```

Close the interface.

```
get_device_identification() → Dict[int, bytes]
```

Query and return the device identification using Modbus function code 43.14.

Returns:
containing key values pairs with the device identifiers

```
get_fifo_queue_content(address: int) → List[int]
```

Query and return the fifo content of `address` using Modbus function code 24.

Parameters:
address – the fifo queue pointer address
Returns:
list of content from the fifo queue at `address`

```
mask_holding_register(reference: int, and_mask: int, or_mask: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Mask write single holding register using Modbus function code 22.

Parameters:

- **reference** – the register reference
- **and_mask** – the and mask
- **or_mask** – the or mask

```
mask_multiple_holding_registers(reference: int, quantity: int, and_mask: int, or_mask: int) → None
```

Mask write multiple holding registers using Modbus function code 16.

Parameters:

- **reference** – the register reference
- **quantity** – the number of registers to be masked
- **and_mask** – the and mask
- **or_mask** – the or mask

```
query(adu: SerialRTUModbusRequest | SerialASCIIModbusRequest | TCPModbusRequest) → SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Query `adu` using the interface and return the decoded response. This method is thread-safe.

Parameters:
adu – a serializable adu
Returns:
the decoded response if no exception occurred
Return type:
adu
Raises:
ModbusException – in case of an exception response

```
read() → SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Read a message from the interface and decode it.

Returns:
the decoded adu as is
Return type:
adu
Raises:
Exception if no answer was received –

```
read_coil(reference: int) → int
```

Read a single coil using Modbus function code 1.

Parameters:

reference – the register reference.
Returns:
`1` if the coil is set and `0` else.

```
read_coil_bitfield(reference: int, length: int) → int
```

Read a bitfield from coil memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_coil_bitfield_list(reference: int, quantity: int, length: int) → List[int]
```

Read a list of bitfields from coil memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_coil_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct] |
Type[ByteType]) → ByteStruct | ByteType
```

Read data from coils using Modbus function code 1.

Parameters:

- **reference** – the coil reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_coil_flag(reference: int) → bool
```

Read a bit from coil memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_coil_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from coil memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_coil_nibble(reference: int) → int
```

Read a nibble from coil memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_coil_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from coil memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_discrete_input(reference: int) → int
```

Read single discrete input using Modbus function code 2.

Parameters:
reference – the register reference.
Returns:
`1` if the discrete input is set and `0` else.

```
read_discrete_input_bitfield(reference: int, length: int) → int
```

Read a bitfield from discrete input memory.

Parameters:

- **reference** – the reference to read from

- **length** – the length of the value

Returns:
int value read from `reference`

```
read_discrete_input_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_discrete_input_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct]
| Type[ByteType]) → ByteStruct | ByteType
```

Read data from discrete inputs using Modbus function code 2.

Parameters:

- **reference** – the discrete input reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_discrete_input_flag(reference: int) → bool
```

Read a bit from discrete input memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_discrete_input_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_discrete_input_nibble(reference: int) → int
```

Read a nibble from discrete input memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_discrete_input_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_extended_memory(memory_number: int, record_number: int, record_length: int) →
List[int]
```

Query and return extended memory from device using Modbus function code 20.

Parameters:

- **memory_number** – the memory number (0x0001 to 0xffff)
- **record_number** – the record to start reading from
- **record_length** – the length of records

Returns:
the read records

```
read_holding_register(reference: int) → int
```

Read a single holding register using Modbus function code 3.

Parameters:
reference – the register reference.
Returns:
the holding register value

```
read_holding_register_bdouble(reference: int) → float
```

Read a double from holding register memory.

Parameters:

reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_bdouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_bfloat(reference: int) → float
```

Read a float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_bfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_bitfield(reference: int, length: int) → int
```

Read a bitfield from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_holding_register_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → ByteStruct | ByteType
```

Read data from holding registers using Modbus function code 3.

Parameters:

- **reference** – the register reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_holding_register_double21436587(reference: int) → float
```

Read a 21436587-endian double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_double21436587_list(reference: int, quantity: int) → List[float]
```

Read a list of 21436587-endian doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_double78563412(reference: int) → float
```

Read a 78563412-endian double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_double78563412_list(reference: int, quantity: int) → List[float]
```

Read a list of 78563412-endian doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_flag(reference: int) → bool
```

Read a bit from holding register memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_holding_register_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_holding_register_float2143(reference: int) → float
```

Read a 2143-endian float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_float2143_list(reference: int, quantity: int) → List[float]
```

Read a list of 2143-endian floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_float3412(reference: int) → float
```

Read a 3412-endian float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_float3412_list(reference: int, quantity: int) → List[float]
```

Read a list of 3412-endian floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_ldouble(reference: int) → float
```

Read a double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_ldouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from holding register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_lfloat(reference: int) → float
```

Read a float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_lfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_nibble(reference: int) → int
```

Read a nibble from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint16(reference: int) → int
```

Read a signed 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint32(reference: int) → int
```

Read a signed 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint64(reference: int) → int
```

Read a signed 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint8(reference: int) → int
```

Read a signed 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint2143(reference: int) → int
```

Read a signed 2143-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint21436587(reference: int) → int
```

Read a signed 21436587-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:

int value read from `reference`

```
read_holding_register_sint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 21436587-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 2143-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint3412(reference: int) → int
```

Read a signed 3412-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 3412-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint78563412(reference: int) → int
```

Read a signed 78563412-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 78563412-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint16(reference: int) → int
```

Read a signed 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint32(reference: int) → int
```

Read a signed 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint64(reference: int) → int
```

Read a signed 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint8(reference: int) → int
```

Read a signed 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_string(reference: int, length: int) → bytes
```

Read a string from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
bytes value read from `reference`

```
read_holding_register_string_list(reference: int, quantity: int, length: int) →
List[bytes]
```

Read a list of strings from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of bytes values read from `reference`

```
read_holding_register_ubint16(reference: int) → int
```

Read an unsigned 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint32(reference: int) → int
```

Read an unsigned 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint64(reference: int) → int
```

Read an unsigned 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint8(reference: int) → int
```

Read an unsigned 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint2143(reference: int) → int
```

Read an unsigned 2143-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint21436587(reference: int) → int
```

Read an unsigned 21436587-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 21436587-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 2143-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint3412(reference: int) → int
```

Read an unsigned 3412-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 3412-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint78563412(reference: int) → int
```

Read an unsigned 78563412-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 78563412-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint16(reference: int) → int
```

Read an unsigned 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:

int value read from `reference`

```
read_holding_register_ulint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint32(reference: int) → int
```

Read an unsigned 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint64(reference: int) → int
```

Read an unsigned 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint8(reference: int) → int
```

Read an unsigned 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register(reference: int) → int
```

Read a single input register using Modbus function code 4.

Parameters:
reference – the register reference.
Returns:
the input register value

```
read_input_register_bdouble(reference: int) → float
```

Read a double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_bdouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_bfloat(reference: int) → float
```

Read a float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_bfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_bitfield(reference: int, length: int) → int
```

Read a bitfield from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_input_register_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct]
| Type[ByteType]) → ByteStruct | ByteType
```

Read data from input registers using Modbus function code 4.

Parameters:

- **reference** – the register reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_input_register_double21436587(reference: int) → float
```

Read a 21436587-endian double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_double21436587_list(reference: int, quantity: int) → List[float]
```

Read a list of 21436587-endian doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_double78563412(reference: int) → float
```

Read a 78563412-endian double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_double78563412_list(reference: int, quantity: int) → List[float]
```

Read a list of 78563412-endian doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_flag(reference: int) → bool
```

Read a bit from input register memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_input_register_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_input_register_float2143(reference: int) → float
```

Read a 2143-endian float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_float2143_list(reference: int, quantity: int) → List[float]
```

Read a list of 2143-endian floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_float3412(reference: int) → float
```

Read a 3412-endian float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_float3412_list(reference: int, quantity: int) → List[float]
```

Read a list of 3412-endian floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_ldouble(reference: int) → float
```

Read a double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_ldouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_lfloat(reference: int) → float
```

Read a float from input register memory.

Parameters:
reference – the reference to read from
Returns:

float value read from `reference`

```
read_input_register_lfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_nibble(reference: int) → int
```

Read a nibble from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint16(reference: int) → int
```

Read a signed 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint32(reference: int) → int
```

Read a signed 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint64(reference: int) → int
```

Read a signed 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint8(reference: int) → int
```

Read a signed 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint2143(reference: int) → int
```

Read a signed 2143-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint21436587(reference: int) → int
```

Read a signed 21436587-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 21436587-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:

list of int values read from `reference`

```
read_input_register_sint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 2143-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint3412(reference: int) → int
```

Read a signed 3412-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 3412-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint78563412(reference: int) → int
```

Read a signed 78563412-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 78563412-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint16(reference: int) → int
```

Read a signed 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint32(reference: int) → int
```

Read a signed 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint64(reference: int) → int
```

Read a signed 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint8(reference: int) → int
```

Read a signed 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_string(reference: int, length: int) → bytes
```

Read a string from input register memory.

Parameters:

- **reference** – the reference to read from

- **length** – the length of the value

Returns:
bytes value read from `reference`

```
read_input_register_string_list(reference: int, quantity: int, length: int) →
List[bytes]
```

Read a list of strings from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of bytes values read from `reference`

```
read_input_register_ubint16(reference: int) → int
```

Read an unsigned 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint32(reference: int) → int
```

Read an unsigned 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint64(reference: int) → int
```

Read an unsigned 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint8(reference: int) → int
```

Read an unsigned 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint2143(reference: int) → int
```

Read an unsigned 2143-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint21436587(reference: int) → int
```

Read an unsigned 21436587-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 21436587-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 2143-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint3412(reference: int) → int
```

Read an unsigned 3412-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 3412-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint78563412(reference: int) → int
```

Read an unsigned 78563412-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 78563412-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint16(reference: int) → int
```

Read an unsigned 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint32(reference: int) → int
```

Read an unsigned 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint64(reference: int) → int
```

Read an unsigned 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint8(reference: int) → int
```

Read an unsigned 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_multiple_coils(reference: int, quantity: int) → List[int]
```

Read multiple coils using Modbus function code 1.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of coils to be read.

Returns:
a list of coil states where each element is `1` if the corresponding coil is set and `0` else.

```
read_multiple_discrete_inputs(reference: int, quantity: int) → List[int]
```

Read multiple discrete inputs using Modbus function code 2.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of discrete inputs to be read.

Returns:
a list of discrete inputs where each element is `1` if the corresponding discrete input is set and `0` else.

```
read_multiple_holding_registers(reference: int, quantity: int) → List[int]
```

Read multiple holding registers using Modbus function code 3.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of registers to be read.

Returns:
the holding register values

```
read_multiple_input_registers(reference: int, quantity: int) → List[int]
```

Read multiple input registers using Modbus function code 4.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of registers to be read.

Returns:
the input register values

```
read_write_multiple_holding_registers(read_reference: int, read_quantity: int,
write_reference: int, write_values: List[int]) → List[int]
```

Read/Write multiple holding registers using Modbus function code 23.

Parameters:

- **read_reference** – the register reference to read from.
- **read_quantity** – the number of registers to read.
- **write_reference** – the register reference to to write to.
- **write_values** – the values to be written.

Returns:
the read registers

```
write(adu: SerialRTUModbusRequest | SerialASCIIModbusRequest | TCPModbusRequest) → None
```

Write `adu` encoded using the interface.

Parameters:
adu – a serializable adu

```
write_coil(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a single coil using Modbus function code 5.

Parameters:

- **reference** – the register reference.
- **value** – the value to be written.

```
write_coil_bitfield(reference: int, value: int, length: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_coil_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_coil_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct] |
Type[ByteType]) → SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write data to coils using Modbus function code 15.

Parameters:

- **reference** – the coil reference.
- **data** – the type or instance or the decoder for the data

```
write_coil_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_coil_flag_list(reference: int, values: List[bool]) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_coil_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_coil_nibble_list(reference: int, values: List[int]) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_extended_memory(memory_number: int, record_number: int, records: List[int]) → None
```

Write extended memory using Modbus function code 21.

Parameters:

- **memory_number** – the memory number (0x0001 to 0xffff)
- **record_number** – the record to write to
- **records** – the records to be written

```
write_holding_register(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write single holding register using Modbus function code 6.

Parameters:

- **reference** – the register reference.
- **value** – the value to be written into the corresponding register.

```
write_holding_register_bdouble(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_bdouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_bfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_bfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_bitfield(reference: int, value: int, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

- **length** – the length of the value

```
write_holding_register_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_holding_register_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → SerialRTUModbusResponse | SerialASCIIModbusResponse |
TCPModbusResponse
```

Write data to holding registers using Modbus function code 16.

Parameters:

- **reference** – the register reference.
- **data** – the type or instance or the decoder for the data

```
write_holding_register_double21436587(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 21436587-endian double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_double21436587_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 21436587-endian doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_double78563412(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 78563412-endian double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_double78563412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 78563412-endian doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_holding_register_flag_list(reference: int, values: List[bool]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_holding_register_float2143(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 2143-endian float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_float2143_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 2143-endian floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_float3412(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 3412-endian float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_float3412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 3412-endian floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_ldouble(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_ldouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_lfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_lfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_nibble_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 2143-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 21436587-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 21436587-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 2143-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 3412-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 3412-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 78563412-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 78563412-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_string(reference: int, value: bytes, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a string to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bytes value to be written
- **length** – the length of the value

```
write_holding_register_string_list(reference: int, values: List[bytes], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of strings to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bytes values to be written
- **length** – the length of the value

```
write_holding_register_ubint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 2143-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 21436587-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 21436587-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 2143-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 3412-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 3412-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 78563412-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 78563412-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_multiple_coils(reference: int, values: List[int]) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write multiple coils using Modbus function code 15.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

```
write_multiple_holding_registers(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write multiple holding registers using Modbus function code 16.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

Serial RTU Client

```
class htf.modbus.ModbusSerialRTUClient(com_port: str, baud: int = 9600, bytesize: int = 8,
parity: str = 'E', stopbits: int = 1, rtscts: bool = False, device_address: int = 1, timeout:
int | float = 1.0, retries: int | None = None, references_start_at_one: bool = True,
request_parser: Type[SerialRTUModbusRequest] | Type[SerialASCIIModbusRequest] |
Type[TCPModbusRequest] = <class 'htf.modbus.protocol.SerialRTUModbusRequest'>,
response_parser: Type[SerialRTUModbusResponse] | Type[SerialASCIIModbusResponse] |
Type[TCPModbusResponse] = <class 'htf.modbus.protocol.SerialRTUModbusResponse'>, debuglevel:
int | None = None)
```

Parameters:

- **com_port** – the com port to be used
- **baud** – the baud rate
- **bytesize** – number of bits in a byte
- **parity** – serial.PARITY_NONE, serial.PARITY_ODD or serial.PARITY_EVEN
- **stopbits** – number of stopbits (1, 1.5 or 2)
- **rtscts** – if True use flow control
- **device_address** – the device address (Slave ID)
- **timeout** – the timeout in seconds
- **retries=None** – the number of retries until an exception is raised
- **references_start_at_one=True** – if set to `True` all references start at `1` else `0`
- **request_parser** – a parser for requests
- **response_parser** – a parser for responses
- **debuglevel** – the debuglevel (`None` disables debug, `1` prints requests and responses and `2` prints introspection)

```
build_request() → SerialRTUModbusRequest | SerialASCIIModbusRequest | TCPModbusRequest
```

Build and return an instance of the desired request parser.

Returns:
request parser

```
build_response() → SerialRTUModbusResponse | SerialASCIIModbusResponse |
TCPModbusResponse
```

Build and return an instance of the desired response parser.

Returns:
response parser

```
clear_counters_and_diagnostic_register() → None
```

Clear counters and diagnostic register using Modbus function code 8.10.

```
clear_overrun_counter_and_flag() → None
```

Clear overrun counter and reset the error flag using Modbus function code 8.20.

```
close() → None
```

Close the interface.

```
disable_broken_checksums() → None
```

Disable broken checksums for testing purposes.

```
echo(data: bytes) → SerialRTUModbusResponse | SerialASCIIModbusResponse |
TCPModbusResponse
```

Query data and return echo using Modbus function code 8.0. An exception is raised if the received data differ from the sent data or the request is too long.

Parameters:
data – The bytes to be sent.
Returns:
response

```
enable_broken_checksums() → None
```

Enable broken checksums for testing purposes.

```
get_bus_character_overrun_count() → int
```

Query and return the bus character overrun count from the device using Modbus function code 8.18.

Returns:
the bus character overrun count

```
get_bus_communication_error_count() → int
```

Query and return the bus communication error count from the device using Modbus function code 8.12.

Returns:
the bus communication error count

```
get_bus_exception_error_count() → int
```

Query and return the bus exception error count from the device using Modbus function code 8.13.

Returns:
the bus exception error count

```
get_bus_message_count() → int
```

Query and return the bus message count from the device using Modbus function code 8.11.

Returns:
the bus message count

```
get_busy_count() → int
```

Query and return the slave busy count from the device using Modbus function code 8.17.

Returns:
the slave busy count

```
get_busy_status() → bool
```

Query and return busy status using Modbus function code 11.

Returns:
busy_status

```
get_communication_event_counter_and_busy_status() → Tuple[int, bool]
```

Query and return communication event counter and busy status using Modbus function code 11.

Returns:
a tuple containing communication_event_counter (int), busy_status (bool)

```
get_device_identification() → Dict[int, bytes]
```

Query and return the device identification using Modbus function code 43.14.

Returns:
containing key values pairs with the device identifiers

```
get_diagnostic_register() → bytes
```

Query and return the diagnostic register using Modbus function 8.2.

Returns:
the content of the diagnostic register

```
get_event_count() → int
```

Query and return event count status using Modbus function code 11.

Returns:
communication_event_counter

```
get_event_log() → Tuple[int, int, int, List[int]]
```

Query and return the event log using Modbus function code 12.

Returns:
a tuple containing busy_status (int), event_count (int), message_count (int), events (list of int)

```
get_exception_status() → int
```

Read and return exception status using Modbus function code 7.

Returns:
the current exception status

```
get_fifo_queue_content(address: int) → List[int]
```

Query and return the fifo content of `address` using Modbus function code 24.

Parameters:
address – the fifo queue pointer address
Returns:
list of content from the fifo queue at `address`

```
get_slave_id() → Tuple[int, bool, bytes]
```

Query and return the slave id using Modbus function code 17.

Returns:
a tuple containing slave-id, running, data

```
get_slave_message_count() → int
```

Query and return the slave message count from the device using Modbus function code 8.14.

Returns:
the slave message count

```
get_slave_nak_count() → int
```

Query and return the slave nak count from the device using Modbus function code 8.16.

Returns:
the slave nak count

```
get_slave_no_response_count() → int
```

Query and return the slave no response count from the device using Modbus function code 8.15.

Returns:
the slave no response count

```
mask_holding_register(reference: int, and_mask: int, or_mask: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Mask write single holding register using Modbus function code 22.

Parameters:

- **reference** – the register reference
- **and_mask** – the and mask
- **or_mask** – the or mask

```
mask_multiple_holding_registers(reference: int, quantity: int, and_mask: int, or_mask: int) → None
```

Mask write multiple holding registers using Modbus function code 16.

Parameters:

- **reference** – the register reference
- **quantity** – the number of registers to be masked
- **and_mask** – the and mask
- **or_mask** – the or mask

```
query(adu: SerialRTUModbusRequest | SerialASCIIModbusRequest | TCPModbusRequest) → SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Query `adu` using the interface and return the decoded response. This method is thread-safe.

Parameters:
adu – a serializable adu
Returns:
the decoded response if no exception occurred
Return type:
adu
Raises:
ModbusException – in case of an exception response

```
read() → SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Read a message from the interface and decode it.

Returns:
the decoded adu as is
Return type:
adu
Raises:
Exception if no answer was received –

```
read_coil(reference: int) → int
```

Read a single coil using Modbus function code 1.

Parameters:
reference – the register reference.
Returns:
`1` if the coil is set and `0` else.

```
read_coil_bitfield(reference: int, length: int) → int
```

Read a bitfield from coil memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_coil_bitfield_list(reference: int, quantity: int, length: int) → List[int]
```

Read a list of bitfields from coil memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_coil_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct] |
Type[ByteType]) → ByteStruct | ByteType
```

Read data from coils using Modbus function code 1.

Parameters:

- **reference** – the coil reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_coil_flag(reference: int) → bool
```

Read a bit from coil memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_coil_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from coil memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_coil_nibble(reference: int) → int
```

Read a nibble from coil memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_coil_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from coil memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_discrete_input(reference: int) → int
```

Read single discrete input using Modbus function code 2.

Parameters:
reference – the register reference.
Returns:
`1` if the discrete input is set and `0` else.

```
read_discrete_input_bitfield(reference: int, length: int) → int
```

Read a bitfield from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_discrete_input_bitfield_list(reference: int, quantity: int, length: int) → List[int]
```

Read a list of bitfields from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_discrete_input_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct] | Type[ByteType]) → ByteStruct | ByteType
```

Read data from discrete inputs using Modbus function code 2.

Parameters:

- **reference** – the discrete input reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_discrete_input_flag(reference: int) → bool
```

Read a bit from discrete input memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_discrete_input_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_discrete_input_nibble(reference: int) → int
```

Read a nibble from discrete input memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_discrete_input_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_extended_memory(memory_number: int, record_number: int, record_length: int) →
List[int]
```

Query and return extended memory from device using Modbus function code 20.

Parameters:

- **memory_number** – the memory number (0x0001 to 0xffff)
- **record_number** – the record to start reading from
- **record_length** – the length of records

Returns:
the read records

```
read_holding_register(reference: int) → int
```

Read a single holding register using Modbus function code 3.

Parameters:
reference – the register reference.
Returns:
the holding register value

```
read_holding_register_bdouble(reference: int) → float
```

Read a double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_bdouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_bfloat(reference: int) → float
```

Read a float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_bfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_bitfield(reference: int, length: int) → int
```

Read a bitfield from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_holding_register_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → ByteStruct | ByteType
```

Read data from holding registers using Modbus function code 3.

Parameters:

- **reference** – the register reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_holding_register_double21436587(reference: int) → float
```

Read a 21436587-endian double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_double21436587_list(reference: int, quantity: int) → List[float]
```

Read a list of 21436587-endian doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_double78563412(reference: int) → float
```

Read a 78563412-endian double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_double78563412_list(reference: int, quantity: int) → List[float]
```

Read a list of 78563412-endian doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_flag(reference: int) → bool
```

Read a bit from holding register memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_holding_register_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_holding_register_float2143(reference: int) → float
```

Read a 2143-endian float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_float2143_list(reference: int, quantity: int) → List[float]
```

Read a list of 2143-endian floats from holding register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_float3412(reference: int) → float
```

Read a 3412-endian float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_float3412_list(reference: int, quantity: int) → List[float]
```

Read a list of 3412-endian floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_ldouble(reference: int) → float
```

Read a double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_ldouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_lfloat(reference: int) → float
```

Read a float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_lfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_nibble(reference: int) → int
```

Read a nibble from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint16(reference: int) → int
```

Read a signed 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint32(reference: int) → int
```

Read a signed 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint64(reference: int) → int
```

Read a signed 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint8(reference: int) → int
```

Read a signed 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint2143(reference: int) → int
```

Read a signed 2143-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint21436587(reference: int) → int
```

Read a signed 21436587-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 21436587-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 2143-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint3412(reference: int) → int
```

Read a signed 3412-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 3412-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint78563412(reference: int) → int
```

Read a signed 78563412-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 78563412-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint16(reference: int) → int
```

Read a signed 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint32(reference: int) → int
```

Read a signed 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint64(reference: int) → int
```

Read a signed 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint8(reference: int) → int
```

Read a signed 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_string(reference: int, length: int) → bytes
```

Read a string from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
bytes value read from `reference`

```
read_holding_register_string_list(reference: int, quantity: int, length: int) →
List[bytes]
```

Read a list of strings from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of bytes values read from `reference`

```
read_holding_register_ubint16(reference: int) → int
```

Read an unsigned 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint32(reference: int) → int
```

Read an unsigned 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from

Returns:
int value read from `reference`

```
read_holding_register_ubint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint64(reference: int) → int
```

Read an unsigned 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint8(reference: int) → int
```

Read an unsigned 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint2143(reference: int) → int
```

Read an unsigned 2143-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint21436587(reference: int) → int
```

Read an unsigned 21436587-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 21436587-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 2143-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint3412(reference: int) → int
```

Read an unsigned 3412-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 3412-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint78563412(reference: int) → int
```

Read an unsigned 78563412-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 78563412-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint16(reference: int) → int
```

Read an unsigned 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:

int value read from `reference`

```
read_holding_register_ulint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint32(reference: int) → int
```

Read an unsigned 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint64(reference: int) → int
```

Read an unsigned 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint8(reference: int) → int
```

Read an unsigned 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register(reference: int) → int
```

Read a single input register using Modbus function code 4.

Parameters:
reference – the register reference.
Returns:
the input register value

```
read_input_register_bdouble(reference: int) → float
```

Read a double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_bdouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_bfloat(reference: int) → float
```

Read a float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_bfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_bitfield(reference: int, length: int) → int
```

Read a bitfield from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_input_register_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct]
| Type[ByteType]) → ByteStruct | ByteType
```

Read data from input registers using Modbus function code 4.

Parameters:

- **reference** – the register reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_input_register_double21436587(reference: int) → float
```

Read a 21436587-endian double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_double21436587_list(reference: int, quantity: int) → List[float]
```

Read a list of 21436587-endian doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_double78563412(reference: int) → float
```

Read a 78563412-endian double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_double78563412_list(reference: int, quantity: int) → List[float]
```

Read a list of 78563412-endian doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_flag(reference: int) → bool
```

Read a bit from input register memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_input_register_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_input_register_float2143(reference: int) → float
```

Read a 2143-endian float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_float2143_list(reference: int, quantity: int) → List[float]
```

Read a list of 2143-endian floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_float3412(reference: int) → float
```

Read a 3412-endian float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_float3412_list(reference: int, quantity: int) → List[float]
```

Read a list of 3412-endian floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_ldouble(reference: int) → float
```

Read a double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_ldouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_lfloat(reference: int) → float
```

Read a float from input register memory.

Parameters:
reference – the reference to read from
Returns:

float value read from `reference`

```
read_input_register_lfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_nibble(reference: int) → int
```

Read a nibble from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint16(reference: int) → int
```

Read a signed 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint32(reference: int) → int
```

Read a signed 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint64(reference: int) → int
```

Read a signed 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint8(reference: int) → int
```

Read a signed 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint2143(reference: int) → int
```

Read a signed 2143-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint21436587(reference: int) → int
```

Read a signed 21436587-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 21436587-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:

list of int values read from `reference`

```
read_input_register_sint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 2143-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint3412(reference: int) → int
```

Read a signed 3412-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 3412-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint78563412(reference: int) → int
```

Read a signed 78563412-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 78563412-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint16(reference: int) → int
```

Read a signed 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint32(reference: int) → int
```

Read a signed 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint64(reference: int) → int
```

Read a signed 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint8(reference: int) → int
```

Read a signed 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_string(reference: int, length: int) → bytes
```

Read a string from input register memory.

Parameters:

- **reference** – the reference to read from

- **length** – the length of the value

Returns:
bytes value read from `reference`

```
read_input_register_string_list(reference: int, quantity: int, length: int) →
List[bytes]
```

Read a list of strings from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of bytes values read from `reference`

```
read_input_register_ubint16(reference: int) → int
```

Read an unsigned 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint32(reference: int) → int
```

Read an unsigned 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint64(reference: int) → int
```

Read an unsigned 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint8(reference: int) → int
```

Read an unsigned 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint2143(reference: int) → int
```

Read an unsigned 2143-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint21436587(reference: int) → int
```

Read an unsigned 21436587-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 21436587-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 2143-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint3412(reference: int) → int
```

Read an unsigned 3412-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 3412-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint78563412(reference: int) → int
```

Read an unsigned 78563412-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 78563412-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint16(reference: int) → int
```

Read an unsigned 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint32(reference: int) → int
```

Read an unsigned 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint64(reference: int) → int
```

Read an unsigned 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint8(reference: int) → int
```

Read an unsigned 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_multiple_coils(reference: int, quantity: int) → List[int]
```

Read multiple coils using Modbus function code 1.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of coils to be read.

Returns:
a list of coil states where each element is `1` if the corresponding coil is set and `0` else.

```
read_multiple_discrete_inputs(reference: int, quantity: int) → List[int]
```

Read multiple discrete inputs using Modbus function code 2.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of discrete inputs to be read.

Returns:
a list of discrete inputs where each element is `1` if the corresponding discrete input is set and `0` else.

```
read_multiple_holding_registers(reference: int, quantity: int) → List[int]
```

Read multiple holding registers using Modbus function code 3.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of registers to be read.

Returns:
the holding register values

```
read_multiple_input_registers(reference: int, quantity: int) → List[int]
```

Read multiple input registers using Modbus function code 4.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of registers to be read.

Returns:
the input register values

```
read_write_multiple_holding_registers(read_reference: int, read_quantity: int,
write_reference: int, write_values: List[int]) → List[int]
```

Read/Write multiple holding registers using Modbus function code 23.

Parameters:

- **read_reference** – the register reference to read from.
- **read_quantity** – the number of registers to read.
- **write_reference** – the register reference to to write to.
- **write_values** – the values to be written.

Returns:
the read registers

```
restart_communications(reset_eventlog: bool = False) → None
```

Restart communications using Modbus function code 8.1.

```
set_device_address(device_address: int) → None
```

Set device address.

Parameters:
device_address – the device address to be used for the next requests.

```
set_listen_only_mode() → None
```

Set listen only mode in server using Modbus function code 8.4.

```
write(adu: SerialRTUModbusRequest | SerialASCIIModbusRequest | TCPModbusRequest) → None
```

Write `adu` encoded using the interface.

Parameters:
adu – a serializable adu

```
write_coil(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a single coil using Modbus function code 5.

Parameters:

- **reference** – the register reference.
- **value** – the value to be written.

```
write_coil_bitfield(reference: int, value: int, length: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_coil_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_coil_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct] |
Type[ByteType]) → SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write data to coils using Modbus function code 15.

Parameters:

- **reference** – the coil reference.
- **data** – the type or instance or the decoder for the data

```
write_coil_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_coil_flag_list(reference: int, values: List[bool]) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_coil_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_coil_nibble_list(reference: int, values: List[int]) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_extended_memory(memory_number: int, record_number: int, records: List[int]) → None
```

Write extended memory using Modbus function code 21.

Parameters:

- **memory_number** – the memory number (0x0001 to 0xffff)
- **record_number** – the record to write to
- **records** – the records to be written

```
write_holding_register(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write single holding register using Modbus function code 6.

Parameters:

- **reference** – the register reference.
- **value** – the value to be written into the corresponding register.

```
write_holding_register_bdouble(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_bdouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_bfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_bfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_bitfield(reference: int, value: int, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_holding_register_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_holding_register_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → SerialRTUModbusResponse | SerialASCIIModbusResponse |
TCPModbusResponse
```

Write data to holding registers using Modbus function code 16.

Parameters:

- **reference** – the register reference.
- **data** – the type or instance or the decoder for the data

```
write_holding_register_double21436587(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 21436587-endian double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_double21436587_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 21436587-endian doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_double78563412(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 78563412-endian double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_double78563412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 78563412-endian doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_holding_register_flag_list(reference: int, values: List[bool]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_holding_register_float2143(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 2143-endian float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_float2143_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 2143-endian floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_float3412(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 3412-endian float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_float3412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 3412-endian floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_ldouble(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_ldouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_lfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_lfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_nibble_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 2143-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 21436587-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 21436587-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 2143-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 3412-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 3412-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 78563412-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 78563412-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_string(reference: int, value: bytes, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a string to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bytes value to be written
- **length** – the length of the value

```
write_holding_register_string_list(reference: int, values: List[bytes], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of strings to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bytes values to be written
- **length** – the length of the value

```
write_holding_register_ubint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 2143-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 21436587-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 21436587-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 2143-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 3412-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 3412-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 78563412-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 78563412-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_multiple_coils(reference: int, values: List[int]) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write multiple coils using Modbus function code 15.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

```
write_multiple_holding_registers(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write multiple holding registers using Modbus function code 16.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

Serial ASCII Client

```
class htf.modbus.ModbusSerialASCIIClient(com_port: str, baud: int = 9600,
bytesize: int = 8, parity: str = 'E', stopbits: int = 1, rtscts: bool = False,
device_address: int = 1, timeout: int | float = 1.0, retries: int | None = None,
references_start_at_one: bool = True, ascii_delimiter: bytes = b'\n', request_parser:
Type[SerialRTUModbusRequest] | Type[SerialASCIIModbusRequest] | Type[TCPModbusRequest] =
<class 'htf.modbus.protocol.SerialASCIIModbusRequest'>, response_parser:
Type[SerialRTUModbusResponse] | Type[SerialASCIIModbusResponse] | Type[TCPModbusResponse] =
<class 'htf.modbus.protocol.SerialASCIIModbusResponse'>, debuglevel: int | None = None)
```

Parameters:

- **com_port** – the com port to be used
- **baud** – the baud rate
- **bytesize** – number of bits in a byte
- **parity** – serial.PARITY_NONE, serial.PARITY_ODD or serial.PARITY_EVEN
- **stopbits** – number of stopbits (1, 1.5 or 2)
- **rtscts** – if True use flow control

- **device_address** – the device address (Slave ID)
- **timeout** – the timeout in seconds
- **retries=None** – the number of retries until an exception is raised
- **references_start_at_one=True** – if set to `True` all references start at `1` else `0`
- **ascii_delimiter** – the ascii delimiter to be used
- **request_parser** – a parser for requests
- **response_parser** – a parser for responses
- **debuglevel** – the debuglevel (`None` disables debug, `1` prints requests and responses and `2` prints introspection)

```
build_request() → SerialRTUModbusRequest | SerialASCIIModbusRequest | TCPModbusRequest
```

Build and return an instance of the desired request parser.

Returns:
request parser

```
build_response() → SerialRTUModbusResponse | SerialASCIIModbusResponse |
TCPModbusResponse
```

Build and return an instance of the desired response parser.

Returns:
response parser

```
change_ascii_delimiter(delimiter: bytes) → None
```

Change ASCII delimiter in the device.

Parameters:
delimiter – the new ASCII delimiter.

```
clear_counters_and_diagnostic_register() → None
```

Clear counters and diagnostic register using Modbus function code 8.10.

```
clear_overrun_counter_and_flag() → None
```

Clear overrun counter and reset the error flag using Modbus function code 8.20.

```
close() → None
```

Close the interface.

```
disable_broken_checksums() → None
```

Disable broken checksums for testing purposes.

```
echo(data: bytes) → SerialRTUModbusResponse | SerialASCIIModbusResponse |
TCPModbusResponse
```

Query data and return echo using Modbus function code 8.0. An exception is raised if the received data differ from the sent data or the request is too long.

Parameters:
data – The bytes to be sent.
Returns:
response

```
enable_broken_checksums() → None
```

Enable broken checksums for testing purposes.

```
get_bus_character_overrun_count() → int
```

Query and return the bus character overrun count from the device using Modbus function code 8.18.

Returns:
the bus character overrun count

```
get_bus_communication_error_count() → int
```

Query and return the bus communication error count from the device using Modbus function code 8.12.

Returns:
the bus communication error count

```
get_bus_exception_error_count() → int
```

Query and return the bus exception error count from the device using Modbus function code 8.13.

Returns:
the bus exception error count

```
get_bus_message_count() → int
```

Query and return the bus message count from the device using Modbus function code 8.11.

Returns:
the bus message count

```
get_busy_count() → int
```

Query and return the slave busy count from the device using Modbus function code 8.17.

Returns:
the slave busy count

```
get_busy_status() → bool
```

Query and return busy status using Modbus function code 11.

Returns:
busy_status

```
get_communication_event_counter_and_busy_status() → Tuple[int, bool]
```

Query and return communication event counter and busy status using Modbus function code 11.

Returns:
a tuple containing communication_event_counter (int), busy_status (bool)

```
get_device_identification() → Dict[int, bytes]
```

Query and return the device identification using Modbus function code 43.14.

Returns:
containing key values pairs with the device identifiers

```
get_diagnostic_register() → bytes
```

Query and return the diagnostic register using Modbus function 8.2.

Returns:
the content of the diagnostic register

```
get_event_count() → int
```

Query and return event count status using Modbus function code 11.

Returns:
communication_event_counter

```
get_event_log() → Tuple[int, int, int, List[int]]
```

Query and return the event log using Modbus function code 12.

Returns:
a tuple containing busy_status (int), event_count (int), message_count (int), events (list of int)

```
get_exception_status() → int
```

Read and return exception status using Modbus function code 7.

Returns:
the current exception status

```
get_fifo_queue_content(address: int) → List[int]
```

Query and return the fifo content of `address` using Modbus function code 24.

Parameters:
address – the fifo queue pointer address
Returns:
list of content from the fifo queue at `address`

```
get_slave_id() → Tuple[int, bool, bytes]
```

Query and return the slave id using Modbus function code 17.

Returns:
a tuple containing slave-id, running, data

```
get_slave_message_count() → int
```

Query and return the slave message count from the device using Modbus function code 8.14.

Returns:
the slave message count

```
get_slave_nak_count() → int
```

Query and return the slave nak count from the device using Modbus function code 8.16.

Returns:
the slave nak count

```
get_slave_no_response_count() → int
```

Query and return the slave no response count from the device using Modbus function code 8.15.

Returns:
the slave no response count

```
mask_holding_register(reference: int, and_mask: int, or_mask: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Mask write single holding register using Modbus function code 22.

Parameters:

- **reference** – the register reference
- **and_mask** – the and mask
- **or_mask** – the or mask

```
mask_multiple_holding_registers(reference: int, quantity: int, and_mask: int, or_mask:
int) → None
```

Mask write multiple holding registers using Modbus function code 16.

Parameters:

- **reference** – the register reference
- **quantity** – the number of registers to be masked
- **and_mask** – the and mask
- **or_mask** – the or mask

```
query(adu: SerialRTUModbusRequest | SerialASCIIModbusRequest | TCPModbusRequest) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Query `adu` using the interface and return the decoded response. This method is thread-safe.

Parameters:
adu – a serializable adu
Returns:
the decoded response if no exception occurred

Return type:
adu
Raises:
ModbusException – in case of an exception response

```
read() → SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Read a message from the interface and decode it.

Returns:
the decoded adu as is
Return type:
adu
Raises:
Exception if no answer was received –

```
read_coil(reference: int) → int
```

Read a single coil using Modbus function code 1.

Parameters:
reference – the register reference.
Returns:
`1` if the coil is set and `0` else.

```
read_coil_bitfield(reference: int, length: int) → int
```

Read a bitfield from coil memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_coil_bitfield_list(reference: int, quantity: int, length: int) → List[int]
```

Read a list of bitfields from coil memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_coil_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct] |
Type[ByteType]) → ByteStruct | ByteType
```

Read data from coils using Modbus function code 1.

Parameters:

- **reference** – the coil reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_coil_flag(reference: int) → bool
```

Read a bit from coil memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_coil_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from coil memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_coil_nibble(reference: int) → int
```

Read a nibble from coil memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_coil_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from coil memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_discrete_input(reference: int) → int
```

Read single discrete input using Modbus function code 2.

Parameters:
reference – the register reference.
Returns:
`1` if the discrete input is set and `0` else.

```
read_discrete_input_bitfield(reference: int, length: int) → int
```

Read a bitfield from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_discrete_input_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_discrete_input_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct]
| Type[ByteType]) → ByteStruct | ByteType
```

Read data from discrete inputs using Modbus function code 2.

Parameters:

- **reference** – the discrete input reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_discrete_input_flag(reference: int) → bool
```

Read a bit from discrete input memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_discrete_input_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_discrete_input_nibble(reference: int) → int
```

Read a nibble from discrete input memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_discrete_input_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_extended_memory(memory_number: int, record_number: int, record_length: int) →
List[int]
```

Query and return extended memory from device using Modbus function code 20.

Parameters:

- **memory_number** – the memory number (0x0001 to 0xffff)

- **record_number** – the record to start reading from
- **record_length** – the length of records

Returns:
the read records

```
read_holding_register(reference: int) → int
```

Read a single holding register using Modbus function code 3.

Parameters:
reference – the register reference.
Returns:
the holding register value

```
read_holding_register_bdouble(reference: int) → float
```

Read a double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_bdouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_bfloat(reference: int) → float
```

Read a float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_bfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_bitfield(reference: int, length: int) → int
```

Read a bitfield from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_holding_register_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → ByteStruct | ByteType
```

Read data from holding registers using Modbus function code 3.

Parameters:

- **reference** – the register reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_holding_register_double21436587(reference: int) → float
```

Read a 21436587-endian double from holding register memory.

Parameters:

reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_double21436587_list(reference: int, quantity: int) → List[float]
```

Read a list of 21436587-endian doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_double78563412(reference: int) → float
```

Read a 78563412-endian double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_double78563412_list(reference: int, quantity: int) → List[float]
```

Read a list of 78563412-endian doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_flag(reference: int) → bool
```

Read a bit from holding register memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_holding_register_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_holding_register_float2143(reference: int) → float
```

Read a 2143-endian float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_float2143_list(reference: int, quantity: int) → List[float]
```

Read a list of 2143-endian floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_float3412(reference: int) → float
```

Read a 3412-endian float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_float3412_list(reference: int, quantity: int) → List[float]
```

Read a list of 3412-endian floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_ldouble(reference: int) → float
```

Read a double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_ldouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_lfloat(reference: int) → float
```

Read a float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_lfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_nibble(reference: int) → int
```

Read a nibble from holding register memory.

Parameters:
reference – the reference to read from
Returns:

int value read from `reference`

```
read_holding_register_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint16(reference: int) → int
```

Read a signed 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint32(reference: int) → int
```

Read a signed 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint64(reference: int) → int
```

Read a signed 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint8(reference: int) → int
```

Read a signed 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint2143(reference: int) → int
```

Read a signed 2143-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint21436587(reference: int) → int
```

Read a signed 21436587-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 21436587-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 2143-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint3412(reference: int) → int
```

Read a signed 3412-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:

int value read from `reference`

```
read_holding_register_sint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 3412-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint78563412(reference: int) → int
```

Read a signed 78563412-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 78563412-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint16(reference: int) → int
```

Read a signed 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint32(reference: int) → int
```

Read a signed 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint64(reference: int) → int
```

Read a signed 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint8(reference: int) → int
```

Read a signed 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_string(reference: int, length: int) → bytes
```

Read a string from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
bytes value read from `reference`

```
read_holding_register_string_list(reference: int, quantity: int, length: int) →
List[bytes]
```

Read a list of strings from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of bytes values read from `reference`

```
read_holding_register_ubint16(reference: int) → int
```

Read an unsigned 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint32(reference: int) → int
```

Read an unsigned 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint64(reference: int) → int
```

Read an unsigned 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint8(reference: int) → int
```

Read an unsigned 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint2143(reference: int) → int
```

Read an unsigned 2143-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint21436587(reference: int) → int
```

Read an unsigned 21436587-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 21436587-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 2143-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint3412(reference: int) → int
```

Read an unsigned 3412-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 3412-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint78563412(reference: int) → int
```

Read an unsigned 78563412-endian 64-bit integer from holding register memory.

Parameters:

reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 78563412-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint16(reference: int) → int
```

Read an unsigned 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint32(reference: int) → int
```

Read an unsigned 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint64(reference: int) → int
```

Read an unsigned 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint8(reference: int) → int
```

Read an unsigned 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register(reference: int) → int
```

Read a single input register using Modbus function code 4.

Parameters:
reference – the register reference.
Returns:
the input register value

```
read_input_register_bdouble(reference: int) → float
```

Read a double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_bdouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_bfloat(reference: int) → float
```

Read a float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_bfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:

list of float values read from `reference`

```
read_input_register_bitfield(reference: int, length: int) → int
```

Read a bitfield from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_input_register_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct]
| Type[ByteType]) → ByteStruct | ByteType
```

Read data from input registers using Modbus function code 4.

Parameters:

- **reference** – the register reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_input_register_double21436587(reference: int) → float
```

Read a 21436587-endian double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_double21436587_list(reference: int, quantity: int) → List[float]
```

Read a list of 21436587-endian doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_double78563412(reference: int) → float
```

Read a 78563412-endian double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_double78563412_list(reference: int, quantity: int) → List[float]
```

Read a list of 78563412-endian doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_flag(reference: int) → bool
```

Read a bit from input register memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_input_register_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from input register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_input_register_float2143(reference: int) → float
```

Read a 2143-endian float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_float2143_list(reference: int, quantity: int) → List[float]
```

Read a list of 2143-endian floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_float3412(reference: int) → float
```

Read a 3412-endian float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_float3412_list(reference: int, quantity: int) → List[float]
```

Read a list of 3412-endian floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_ldouble(reference: int) → float
```

Read a double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_ldouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_lfloat(reference: int) → float
```

Read a float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_lfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_nibble(reference: int) → int
```

Read a nibble from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint16(reference: int) → int
```

Read a signed 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint32(reference: int) → int
```

Read a signed 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint64(reference: int) → int
```

Read a signed 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint8(reference: int) → int
```

Read a signed 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint2143(reference: int) → int
```

Read a signed 2143-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint21436587(reference: int) → int
```

Read a signed 21436587-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 21436587-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 2143-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint3412(reference: int) → int
```

Read a signed 3412-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 3412-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint78563412(reference: int) → int
```

Read a signed 78563412-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 78563412-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint16(reference: int) → int
```

Read a signed 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint32(reference: int) → int
```

Read a signed 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint64(reference: int) → int
```

Read a signed 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint8(reference: int) → int
```

Read a signed 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_string(reference: int, length: int) → bytes
```

Read a string from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
bytes value read from `reference`

```
read_input_register_string_list(reference: int, quantity: int, length: int) →
List[bytes]
```

Read a list of strings from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of bytes values read from `reference`

```
read_input_register_ubint16(reference: int) → int
```

Read an unsigned 16-bit integer from input register memory.

Parameters:
reference – the reference to read from

Returns:
int value read from `reference`

```
read_input_register_ubint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint32(reference: int) → int
```

Read an unsigned 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint64(reference: int) → int
```

Read an unsigned 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint8(reference: int) → int
```

Read an unsigned 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint2143(reference: int) → int
```

Read an unsigned 2143-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint21436587(reference: int) → int
```

Read an unsigned 21436587-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 21436587-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 2143-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint3412(reference: int) → int
```

Read an unsigned 3412-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 3412-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint78563412(reference: int) → int
```

Read an unsigned 78563412-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 78563412-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint16(reference: int) → int
```

Read an unsigned 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint32(reference: int) → int
```

Read an unsigned 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint64(reference: int) → int
```

Read an unsigned 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint8(reference: int) → int
```

Read an unsigned 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_multiple_coils(reference: int, quantity: int) → List[int]
```

Read multiple coils using Modbus function code 1.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of coils to be read.

Returns:
a list of coil states where each element is `1` if the corresponding coil is set and `0` else.

```
read_multiple_discrete_inputs(reference: int, quantity: int) → List[int]
```

Read multiple discrete inputs using Modbus function code 2.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of discrete inputs to be read.

Returns:
a list of discrete inputs where each element is `1` if the corresponding discrete input is set and `0` else.

```
read_multiple_holding_registers(reference: int, quantity: int) → List[int]
```

Read multiple holding registers using Modbus function code 3.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of registers to be read.

Returns:
the holding register values

```
read_multiple_input_registers(reference: int, quantity: int) → List[int]
```

Read multiple input registers using Modbus function code 4.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of registers to be read.

Returns:
the input register values

```
read_write_multiple_holding_registers(read_reference: int, read_quantity: int,
write_reference: int, write_values: List[int]) → List[int]
```

Read/Write multiple holding registers using Modbus function code 23.

Parameters:

- **read_reference** – the register reference to read from.
- **read_quantity** – the number of registers to read.
- **write_reference** – the register reference to to write to.
- **write_values** – the values to be written.

Returns:
the read registers

```
restart_communications(reset_eventlog: bool = False) → None
```

Restart communications using Modbus function code 8.1.

```
set_device_address(device_address: int) → None
```

Set device address.

Parameters:
device_address – the device address to be used for the next requests.

```
set_listen_only_mode() → None
```

Set listen only mode in server using Modbus function code 8.4.

```
write(adu: SerialRTUModbusRequest | SerialASCIIModbusRequest | TCPModbusRequest) → None
```

Write `adu` encoded using the interface.

Parameters:
adu – a serializable adu

```
write_coil(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a single coil using Modbus function code 5.

Parameters:

- **reference** – the register reference.
- **value** – the value to be written.

```
write_coil_bitfield(reference: int, value: int, length: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_coil_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_coil_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct] |
Type[ByteType]) → SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write data to coils using Modbus function code 15.

Parameters:

- **reference** – the coil reference.
- **data** – the type or instance or the decoder for the data

```
write_coil_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_coil_flag_list(reference: int, values: List[bool]) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_coil_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_coil_nibble_list(reference: int, values: List[int]) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_extended_memory(memory_number: int, record_number: int, records: List[int]) → None
```

Write extended memory using Modbus function code 21.

Parameters:

- **memory_number** – the memory number (0x0001 to 0xffff)
- **record_number** – the record to write to
- **records** – the records to be written

```
write_holding_register(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write single holding register using Modbus function code 6.

Parameters:

- **reference** – the register reference.
- **value** – the value to be written into the corresponding register.

```
write_holding_register_bdouble(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_bdouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_bfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_bfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_bitfield(reference: int, value: int, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_holding_register_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to holding register memory.

Parameters:

- **reference** – the reference to write to

- **values** – a list of int values to be written
- **length** – the length of the value

```
write_holding_register_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → SerialRTUModbusResponse | SerialASCIIModbusResponse |
TCPModbusResponse
```

Write data to holding registers using Modbus function code 16.

Parameters:

- **reference** – the register reference.
- **data** – the type or instance or the decoder for the data

```
write_holding_register_double21436587(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 21436587-endian double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_double21436587_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 21436587-endian doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_double78563412(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 78563412-endian double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_double78563412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 78563412-endian doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_holding_register_flag_list(reference: int, values: List[bool]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_holding_register_float2143(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 2143-endian float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_float2143_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 2143-endian floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_float3412(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 3412-endian float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_float3412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 3412-endian floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_ldouble(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_ldouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_lfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_lfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_nibble_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 2143-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 21436587-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 21436587-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 2143-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 3412-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 3412-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 78563412-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 78563412-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_string(reference: int, value: bytes, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a string to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bytes value to be written
- **length** – the length of the value

```
write_holding_register_string_list(reference: int, values: List[bytes], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of strings to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bytes values to be written
- **length** – the length of the value

```
write_holding_register_ubint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 2143-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 21436587-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 21436587-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 2143-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 3412-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 3412-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 78563412-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 78563412-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_multiple_coils(reference: int, values: List[int]) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write multiple coils using Modbus function code 15.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

```
write_multiple_holding_registers(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write multiple holding registers using Modbus function code 16.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

TCP Client

```
class htf.modbus.ModbusTCPClient(address: str, port: int = 502, unit_identifier: int = 0,
timeout: int | float = 1.0, retries: int | None = None, references_start_at_one: bool = True,
transaction_identifier: int = 0, auto_disconnect: bool = False, request_parser:
Type[SerialRTUModbusRequest] | Type[SerialASCIIModbusRequest] | Type[TCPModbusRequest] =
<class 'htf.modbus.protocol.TCPModbusRequest'>, response_parser:
Type[SerialRTUModbusResponse] | Type[SerialASCIIModbusResponse] | Type[TCPModbusResponse] =
<class 'htf.modbus.protocol.TCPModbusResponse'>, debuglevel: int | None = None)
```

Parameters:

- **address** – the ip address to connect to
- **port** – the port to be used
- **unit_identifier** – the unit identifier for Modbus TCP
- **timeout** – the timeout in seconds
- **retries=None** – the number of retries until an exception is raised
- **references_start_at_one=True** – if set to `True` all references start at `1` else `0`
- **transaction_identifier** – the initial transaction identifier
- **auto_disconnect=False** – if set to `True` the TCP connection is closed immediately and re-opened on next request
- **request_parser** – a parser for requests
- **response_parser** – a parser for responses
- **debuglevel** – the debuglevel (`None` disables debug, `1` prints requests and responses and `2` prints introspection)

```
build_request() → SerialRTUModbusRequest | SerialASCIIModbusRequest | TCPModbusRequest
```

Build and return an instance of the desired request parser.

Returns:
request parser

```
build_response() → SerialRTUModbusResponse | SerialASCIIModbusResponse |
TCPModbusResponse
```

Build and return an instance of the desired response parser.

Returns:
response parser

```
close() → None
```

Close the interface.

```
get_device_identification() → Dict[int, bytes]
```

Query and return the device identification using Modbus function code 43.14.

Returns:
containing key values pairs with the device identifiers

```
get_fifo_queue_content(address: int) → List[int]
```

Query and return the fifo content of `address` using Modbus function code 24.

Parameters:
address – the fifo queue pointer address
Returns:
list of content from the fifo queue at `address`

```
get_transaction_identifier() → int
```

Create and return a new transaction identifer. Is thread-safe.

Returns:
the next transaction identifier

```
mask_holding_register(reference: int, and_mask: int, or_mask: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Mask write single holding register using Modbus function code 22.

Parameters:

- **reference** – the register reference
- **and_mask** – the and mask
- **or_mask** – the or mask

```
mask_multiple_holding_registers(reference: int, quantity: int, and_mask: int, or_mask:
int) → None
```

Mask write multiple holding registers using Modbus function code 16.

Parameters:

- **reference** – the register reference
- **quantity** – the number of registers to be masked
- **and_mask** – the and mask
- **or_mask** – the or mask

```
query(adu: SerialRTUModbusRequest | SerialASCIIModbusRequest | TCPModbusRequest) → SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Query `adu` using the interface and return the decoded response.

Parameters:
adu – a serializable adu
Returns:
the decoded response if no exception occurred
Return type:
adu
Raises:
ModbusException – in case of an exception response

```
read() → SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Read a message from the interface and decode it.

Returns:
the decoded adu as is
Return type:
adu
Raises:
Exception if no answer was received –

```
read_coil(reference: int) → int
```

Read a single coil using Modbus function code 1.

Parameters:
reference – the register reference.
Returns:
`1` if the coil is set and `0` else.

```
read_coil_bitfield(reference: int, length: int) → int
```

Read a bitfield from coil memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_coil_bitfield_list(reference: int, quantity: int, length: int) → List[int]
```

Read a list of bitfields from coil memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_coil_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct] |
Type[ByteType]) → ByteStruct | ByteType
```

Read data from coils using Modbus function code 1.

Parameters:

- **reference** – the coil reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_coil_flag(reference: int) → bool
```

Read a bit from coil memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_coil_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from coil memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_coil_nibble(reference: int) → int
```

Read a nibble from coil memory.

Parameters:
reference – the reference to read from

Returns:
int value read from `reference`

```
read_coil_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from coil memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_discrete_input(reference: int) → int
```

Read single discrete input using Modbus function code 2.

Parameters:
reference – the register reference.
Returns:
`1` if the discrete input is set and `0` else.

```
read_discrete_input_bitfield(reference: int, length: int) → int
```

Read a bitfield from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_discrete_input_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_discrete_input_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct]
| Type[ByteType]) → ByteStruct | ByteType
```

Read data from discrete inputs using Modbus function code 2.

Parameters:

- **reference** – the discrete input reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_discrete_input_flag(reference: int) → bool
```

Read a bit from discrete input memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_discrete_input_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_discrete_input_nibble(reference: int) → int
```

Read a nibble from discrete input memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_discrete_input_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from discrete input memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_extended_memory(memory_number: int, record_number: int, record_length: int) →
List[int]
```

Query and return extended memory from device using Modbus function code 20.

Parameters:

- **memory_number** – the memory number (0x0001 to 0xffff)
- **record_number** – the record to start reading from
- **record_length** – the length of records

Returns:
the read records

```
read_holding_register(reference: int) → int
```

Read a single holding register using Modbus function code 3.

Parameters:
reference – the register reference.
Returns:
the holding register value

```
read_holding_register_bdouble(reference: int) → float
```

Read a double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_bdouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_bfloat(reference: int) → float
```

Read a float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_bfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_bitfield(reference: int, length: int) → int
```

Read a bitfield from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_holding_register_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → ByteStruct | ByteType
```

Read data from holding registers using Modbus function code 3.

Parameters:

- **reference** – the register reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_holding_register_double21436587(reference: int) → float
```

Read a 21436587-endian double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_double21436587_list(reference: int, quantity: int) → List[float]
```

Read a list of 21436587-endian doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_double78563412(reference: int) → float
```

Read a 78563412-endian double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_double78563412_list(reference: int, quantity: int) → List[float]
```

Read a list of 78563412-endian doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_flag(reference: int) → bool
```

Read a bit from holding register memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_holding_register_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_holding_register_float2143(reference: int) → float
```

Read a 2143-endian float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_float2143_list(reference: int, quantity: int) → List[float]
```

Read a list of 2143-endian floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_float3412(reference: int) → float
```

Read a 3412-endian float from holding register memory.

Parameters:
reference – the reference to read from
Returns:

float value read from `reference`

```
read_holding_register_float3412_list(reference: int, quantity: int) → List[float]
```

Read a list of 3412-endian floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_ldouble(reference: int) → float
```

Read a double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_ldouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_lfloat(reference: int) → float
```

Read a float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_lfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_nibble(reference: int) → int
```

Read a nibble from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint16(reference: int) → int
```

Read a signed 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint32(reference: int) → int
```

Read a signed 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint64(reference: int) → int
```

Read a signed 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint8(reference: int) → int
```

Read a signed 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:

int value read from `reference`

```
read_holding_register_sbint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint2143(reference: int) → int
```

Read a signed 2143-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint21436587(reference: int) → int
```

Read a signed 21436587-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 21436587-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 2143-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint3412(reference: int) → int
```

Read a signed 3412-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 3412-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint78563412(reference: int) → int
```

Read a signed 78563412-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 78563412-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint16(reference: int) → int
```

Read a signed 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint32(reference: int) → int
```

Read a signed 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint64(reference: int) → int
```

Read a signed 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:

int value read from `reference`

```
read_holding_register_slint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint8(reference: int) → int
```

Read a signed 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_string(reference: int, length: int) → bytes
```

Read a string from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
bytes value read from `reference`

```
read_holding_register_string_list(reference: int, quantity: int, length: int) →
List[bytes]
```

Read a list of strings from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of bytes values read from `reference`

```
read_holding_register_ubint16(reference: int) → int
```

Read an unsigned 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint32(reference: int) → int
```

Read an unsigned 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:

list of int values read from `reference`

```
read_holding_register_ubint64(reference: int) → int
```

Read an unsigned 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint8(reference: int) → int
```

Read an unsigned 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint2143(reference: int) → int
```

Read an unsigned 2143-endian 32-bit integer from holding register memory.

Parameters:

reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint21436587(reference: int) → int
```

Read an unsigned 21436587-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 21436587-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 2143-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint3412(reference: int) → int
```

Read an unsigned 3412-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 3412-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint78563412(reference: int) → int
```

Read an unsigned 78563412-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 78563412-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint16(reference: int) → int
```

Read an unsigned 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint32(reference: int) → int
```

Read an unsigned 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint64(reference: int) → int
```

Read an unsigned 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint8(reference: int) → int
```

Read an unsigned 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:

int value read from `reference`

```
read_holding_register_ulint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register(reference: int) → int
```

Read a single input register using Modbus function code 4.

Parameters:
reference – the register reference.
Returns:
the input register value

```
read_input_register_bdouble(reference: int) → float
```

Read a double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_bdouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_bfloat(reference: int) → float
```

Read a float from input register memory.

Parameters:

reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_bfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_bitfield(reference: int, length: int) → int
```

Read a bitfield from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_input_register_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct]
| Type[ByteType]) → ByteStruct | ByteType
```

Read data from input registers using Modbus function code 4.

Parameters:

- **reference** – the register reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_input_register_double21436587(reference: int) → float
```

Read a 21436587-endian double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_double21436587_list(reference: int, quantity: int) → List[float]
```

Read a list of 21436587-endian doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_double78563412(reference: int) → float
```

Read a 78563412-endian double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_double78563412_list(reference: int, quantity: int) → List[float]
```

Read a list of 78563412-endian doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_flag(reference: int) → bool
```

Read a bit from input register memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_input_register_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_input_register_float2143(reference: int) → float
```

Read a 2143-endian float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_float2143_list(reference: int, quantity: int) → List[float]
```

Read a list of 2143-endian floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_float3412(reference: int) → float
```

Read a 3412-endian float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_float3412_list(reference: int, quantity: int) → List[float]
```

Read a list of 3412-endian floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_ldouble(reference: int) → float
```

Read a double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_ldouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_lfloat(reference: int) → float
```

Read a float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_lfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_nibble(reference: int) → int
```

Read a nibble from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint16(reference: int) → int
```

Read a signed 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint32(reference: int) → int
```

Read a signed 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:

int value read from `reference`

```
read_input_register_sbint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint64(reference: int) → int
```

Read a signed 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint8(reference: int) → int
```

Read a signed 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint2143(reference: int) → int
```

Read a signed 2143-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint21436587(reference: int) → int
```

Read a signed 21436587-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 21436587-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 2143-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint3412(reference: int) → int
```

Read a signed 3412-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 3412-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint78563412(reference: int) → int
```

Read a signed 78563412-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 78563412-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint16(reference: int) → int
```

Read a signed 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:

int value read from `reference`

```
read_input_register_slint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint32(reference: int) → int
```

Read a signed 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint64(reference: int) → int
```

Read a signed 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint8(reference: int) → int
```

Read a signed 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_string(reference: int, length: int) → bytes
```

Read a string from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
bytes value read from `reference`

```
read_input_register_string_list(reference: int, quantity: int, length: int) →
List[bytes]
```

Read a list of strings from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of bytes values read from `reference`

```
read_input_register_ubint16(reference: int) → int
```

Read an unsigned 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint32(reference: int) → int
```

Read an unsigned 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint64(reference: int) → int
```

Read an unsigned 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint8(reference: int) → int
```

Read an unsigned 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint2143(reference: int) → int
```

Read an unsigned 2143-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint21436587(reference: int) → int
```

Read an unsigned 21436587-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 21436587-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 2143-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint3412(reference: int) → int
```

Read an unsigned 3412-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 3412-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint78563412(reference: int) → int
```

Read an unsigned 78563412-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 78563412-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint16(reference: int) → int
```

Read an unsigned 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint32(reference: int) → int
```

Read an unsigned 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:

int value read from `reference`

```
read_input_register_ulint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint64(reference: int) → int
```

Read an unsigned 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint8(reference: int) → int
```

Read an unsigned 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_multiple_coils(reference: int, quantity: int) → List[int]
```

Read multiple coils using Modbus function code 1.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of coils to be read.

Returns:
a list of coil states where each element is `1` if the corresponding coil is set and `0` else.

```
read_multiple_discrete_inputs(reference: int, quantity: int) → List[int]
```

Read multiple discrete inputs using Modbus function code 2.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of discrete inputs to be read.

Returns:
a list of discrete inputs where each element is `1` if the corresponding discrete input is set and `0` else.

```
read_multiple_holding_registers(reference: int, quantity: int) → List[int]
```

Read multiple holding registers using Modbus function code 3.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of registers to be read.

Returns:
the holding register values

```
read_multiple_input_registers(reference: int, quantity: int) → List[int]
```

Read multiple input registers using Modbus function code 4.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of registers to be read.

Returns:

the input register values

```
read_write_multiple_holding_registers(read_reference: int, read_quantity: int,
write_reference: int, write_values: List[int]) → List[int]
```

Read/Write multiple holding registers using Modbus function code 23.

Parameters:

- **read_reference** – the register reference to read from.
- **read_quantity** – the number of registers to read.
- **write_reference** – the register reference to to write to.
- **write_values** – the values to be written.

Returns:
the read registers

```
reconnect() → None
```

Reconnect socket.

```
write(adu: SerialRTUModbusRequest | SerialASCIIModbusRequest | TCPModbusRequest,
auto_length: bool = True) → None
```

Write `adu` encoded using the interface. The transaction identifier is set automatically. The unit identifier is put into the adu automatically, too.

Parameters:

- **adu** – a serializable adu
- **auto_length=True** – if set to `True` the length is calculated automatically

```
write_coil(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a single coil using Modbus function code 5.

Parameters:

- **reference** – the register reference.
- **value** – the value to be written.

```
write_coil_bitfield(reference: int, value: int, length: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_coil_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_coil_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct] |
Type[ByteType]) → SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write data to coils using Modbus function code 15.

Parameters:

- **reference** – the coil reference.
- **data** – the type or instance or the decoder for the data

```
write_coil_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_coil_flag_list(reference: int, values: List[bool]) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_coil_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_coil_nibble_list(reference: int, values: List[int]) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_extended_memory(memory_number: int, record_number: int, records: List[int]) → None
```

Write extended memory using Modbus function code 21.

Parameters:

- **memory_number** – the memory number (0x0001 to 0xffff)
- **record_number** – the record to write to
- **records** – the records to be written

```
write_holding_register(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write single holding register using Modbus function code 6.

Parameters:

- **reference** – the register reference.
- **value** – the value to be written into the corresponding register.

```
write_holding_register_bdouble(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_bdouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_bfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_bfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_bitfield(reference: int, value: int, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_holding_register_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to holding register memory.

Parameters:

- **reference** – the reference to write to

- **values** – a list of int values to be written
- **length** – the length of the value

```
write_holding_register_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → SerialRTUModbusResponse | SerialASCIIModbusResponse |
TCPModbusResponse
```

Write data to holding registers using Modbus function code 16.

Parameters:

- **reference** – the register reference.
- **data** – the type or instance or the decoder for the data

```
write_holding_register_double21436587(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 21436587-endian double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_double21436587_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 21436587-endian doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_double78563412(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 78563412-endian double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_double78563412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 78563412-endian doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_holding_register_flag_list(reference: int, values: List[bool]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_holding_register_float2143(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 2143-endian float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_float2143_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 2143-endian floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_float3412(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 3412-endian float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_float3412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 3412-endian floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_ldouble(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_ldouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_lfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_lfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_nibble_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 2143-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 21436587-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 21436587-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 2143-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 3412-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 3412-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 78563412-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 78563412-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_string(reference: int, value: bytes, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a string to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bytes value to be written
- **length** – the length of the value

```
write_holding_register_string_list(reference: int, values: List[bytes], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of strings to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bytes values to be written
- **length** – the length of the value

```
write_holding_register_ubint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 2143-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 21436587-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 21436587-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 2143-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 3412-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 3412-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 78563412-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 78563412-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_multiple_coils(reference: int, values: List[int]) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write multiple coils using Modbus function code 15.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

```
write_multiple_holding_registers(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write multiple holding registers using Modbus function code 16.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

TLS Client

```
class htf.modbus.ModbusTLSClient(address: str, port: int = 502, unit_identifier: int = 0,
timeout: int | float = 1.0, retries: int | None = None, references_start_at_one: bool = True,
transaction_identifier: int = 0, auto_disconnect: bool = False, verify: bool = True, cafile:
str | None = None, capath: str | None = None, cadata: str | None = None, request_parser:
Type[SerialRTUModbusRequest] | Type[SerialASCIIModbusRequest] | Type[TCPModbusRequest] =
<class 'htf.modbus.protocol.TCPModbusRequest'>, response_parser:
Type[SerialRTUModbusResponse] | Type[SerialASCIIModbusResponse] | Type[TCPModbusResponse] =
<class 'htf.modbus.protocol.TCPModbusResponse'>, debuglevel: int | None = None)
```

Parameters:

- **address** – the ip address to connect to
- **port** – the port to be used
- **unit_identifier** – the unit identifier for Modbus TCP
- **timeout** – the timeout in seconds
- **retries=None** – the number of retries until an exception is raised
- **references_start_at_one=True** – if set to `True` all references start at `1` else `0`
- **transaction_identifier** – the initial transaction identifier
- **auto_disconnect=False** – if set to `True` the TCP connection is closed immediately and re-opened on next request
- **cafile** – path to a file of concatenated CA certificates in PEM format
- **capath** – path to a directory containing several CA certificates in PEM format
- **cadata** – either an ASCII string of one or more PEM-encoded certificates or a bytes-like object of DER-encoded certificates
- **request_parser** – a parser for requests
- **response_parser** – a parser for responses
- **debuglevel** – the debuglevel (`None` disables debug, `1` prints requests and responses and `2` prints introspection)

```
build_request() → SerialRTUModbusRequest | SerialASCIIModbusRequest | TCPModbusRequest
```

Build and return an instance of the desired request parser.

Returns:
request parser

```
build_response() → SerialRTUModbusResponse | SerialASCIIModbusResponse |
TCPModbusResponse
```

Build and return an instance of the desired response parser.

Returns:
response parser

```
close() → None
```

Close the interface.

```
get_device_identification() → Dict[int, bytes]
```

Query and return the device identification using Modbus function code 43.14.

Returns:
containing key values pairs with the device identifiers

```
get_fifo_queue_content(address: int) → List[int]
```

Query and return the fifo content of `address` using Modbus function code 24.

Parameters:
address – the fifo queue pointer address
Returns:
list of content from the fifo queue at `address`

```
get_transaction_identifier() → int
```

Create and return a new transaction identifer. Is thread-safe.

Returns:
the next transaction identifier

```
mask_holding_register(reference: int, and_mask: int, or_mask: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Mask write single holding register using Modbus function code 22.

Parameters:

- **reference** – the register reference
- **and_mask** – the and mask
- **or_mask** – the or mask

```
mask_multiple_holding_registers(reference: int, quantity: int, and_mask: int, or_mask:
int) → None
```

Mask write multiple holding registers using Modbus function code 16.

Parameters:

- **reference** – the register reference

- **quantity** – the number of registers to be masked
- **and_mask** – the and mask
- **or_mask** – the or mask

```
query(adu: SerialRTUModbusRequest | SerialASCIIModbusRequest | TCPModbusRequest) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Query `adu` using the interface and return the decoded response.

Parameters:
adu – a serializable adu
Returns:
the decoded response if no exception occurred
Return type:
adu
Raises:
ModbusException – in case of an exception response

```
read() → SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Read a message from the interface and decode it.

Returns:
the decoded adu as is
Return type:
adu
Raises:
Exception if no answer was received –

```
read_coil(reference: int) → int
```

Read a single coil using Modbus function code 1.

Parameters:
reference – the register reference.
Returns:
`1` if the coil is set and `0` else.

```
read_coil_bitfield(reference: int, length: int) → int
```

Read a bitfield from coil memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:

int value read from `reference`

```
read_coil_bitfield_list(reference: int, quantity: int, length: int) → List[int]
```

Read a list of bitfields from coil memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_coil_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct] |
Type[ByteType]) → ByteStruct | ByteType
```

Read data from coils using Modbus function code 1.

Parameters:

- **reference** – the coil reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_coil_flag(reference: int) → bool
```

Read a bit from coil memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_coil_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from coil memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_coil_nibble(reference: int) → int
```

Read a nibble from coil memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_coil_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from coil memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_discrete_input(reference: int) → int
```

Read single discrete input using Modbus function code 2.

Parameters:
reference – the register reference.
Returns:
`1` if the discrete input is set and `0` else.

```
read_discrete_input_bitfield(reference: int, length: int) → int
```

Read a bitfield from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_discrete_input_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from discrete input memory.

Parameters:

- **reference** – the reference to read from

- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_discrete_input_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct]
| Type[ByteType]) → ByteStruct | ByteType
```

Read data from discrete inputs using Modbus function code 2.

Parameters:

- **reference** – the discrete input reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_discrete_input_flag(reference: int) → bool
```

Read a bit from discrete input memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_discrete_input_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_discrete_input_nibble(reference: int) → int
```

Read a nibble from discrete input memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_discrete_input_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_extended_memory(memory_number: int, record_number: int, record_length: int) →
List[int]
```

Query and return extended memory from device using Modbus function code 20.

Parameters:

- **memory_number** – the memory number (0x0001 to 0xffff)
- **record_number** – the record to start reading from
- **record_length** – the length of records

Returns:
the read records

```
read_holding_register(reference: int) → int
```

Read a single holding register using Modbus function code 3.

Parameters:
reference – the register reference.
Returns:
the holding register value

```
read_holding_register_bdouble(reference: int) → float
```

Read a double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_bdouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_bfloat(reference: int) → float
```

Read a float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_bfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_bitfield(reference: int, length: int) → int
```

Read a bitfield from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_holding_register_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → ByteStruct | ByteType
```

Read data from holding registers using Modbus function code 3.

Parameters:

- **reference** – the register reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_holding_register_double21436587(reference: int) → float
```

Read a 21436587-endian double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_double21436587_list(reference: int, quantity: int) → List[float]
```

Read a list of 21436587-endian doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_double78563412(reference: int) → float
```

Read a 78563412-endian double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_double78563412_list(reference: int, quantity: int) → List[float]
```

Read a list of 78563412-endian doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_flag(reference: int) → bool
```

Read a bit from holding register memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_holding_register_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_holding_register_float2143(reference: int) → float
```

Read a 2143-endian float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_float2143_list(reference: int, quantity: int) → List[float]
```

Read a list of 2143-endian floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_float3412(reference: int) → float
```

Read a 3412-endian float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_float3412_list(reference: int, quantity: int) → List[float]
```

Read a list of 3412-endian floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_ldouble(reference: int) → float
```

Read a double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_ldouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_lfloat(reference: int) → float
```

Read a float from holding register memory.

Parameters:
reference – the reference to read from
Returns:

float value read from `reference`

```
read_holding_register_lfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_nibble(reference: int) → int
```

Read a nibble from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint16(reference: int) → int
```

Read a signed 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint32(reference: int) → int
```

Read a signed 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint64(reference: int) → int
```

Read a signed 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint8(reference: int) → int
```

Read a signed 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint2143(reference: int) → int
```

Read a signed 2143-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint21436587(reference: int) → int
```

Read a signed 21436587-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 21436587-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:

list of int values read from `reference`

```
read_holding_register_sint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 2143-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint3412(reference: int) → int
```

Read a signed 3412-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 3412-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint78563412(reference: int) → int
```

Read a signed 78563412-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 78563412-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint16(reference: int) → int
```

Read a signed 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint32(reference: int) → int
```

Read a signed 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint64(reference: int) → int
```

Read a signed 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint8(reference: int) → int
```

Read a signed 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_string(reference: int, length: int) → bytes
```

Read a string from holding register memory.

Parameters:

- **reference** – the reference to read from

- **length** – the length of the value

Returns:
bytes value read from `reference`

```
read_holding_register_string_list(reference: int, quantity: int, length: int) →
List[bytes]
```

Read a list of strings from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of bytes values read from `reference`

```
read_holding_register_ubint16(reference: int) → int
```

Read an unsigned 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint32(reference: int) → int
```

Read an unsigned 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint64(reference: int) → int
```

Read an unsigned 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint8(reference: int) → int
```

Read an unsigned 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint2143(reference: int) → int
```

Read an unsigned 2143-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint21436587(reference: int) → int
```

Read an unsigned 21436587-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 21436587-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 2143-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint3412(reference: int) → int
```

Read an unsigned 3412-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 3412-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint78563412(reference: int) → int
```

Read an unsigned 78563412-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 78563412-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint16(reference: int) → int
```

Read an unsigned 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint32(reference: int) → int
```

Read an unsigned 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint64(reference: int) → int
```

Read an unsigned 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint8(reference: int) → int
```

Read an unsigned 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register(reference: int) → int
```

Read a single input register using Modbus function code 4.

Parameters:
reference – the register reference.
Returns:
the input register value

```
read_input_register_bdouble(reference: int) → float
```

Read a double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_bdouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_bfloat(reference: int) → float
```

Read a float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_bfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_bitfield(reference: int, length: int) → int
```

Read a bitfield from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_input_register_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct]
| Type[ByteType]) → ByteStruct | ByteType
```

Read data from input registers using Modbus function code 4.

Parameters:

- **reference** – the register reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_input_register_double21436587(reference: int) → float
```

Read a 21436587-endian double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_double21436587_list(reference: int, quantity: int) → List[float]
```

Read a list of 21436587-endian doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_double78563412(reference: int) → float
```

Read a 78563412-endian double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_double78563412_list(reference: int, quantity: int) → List[float]
```

Read a list of 78563412-endian doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_flag(reference: int) → bool
```

Read a bit from input register memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_input_register_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_input_register_float2143(reference: int) → float
```

Read a 2143-endian float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_float2143_list(reference: int, quantity: int) → List[float]
```

Read a list of 2143-endian floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_float3412(reference: int) → float
```

Read a 3412-endian float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_float3412_list(reference: int, quantity: int) → List[float]
```

Read a list of 3412-endian floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_ldouble(reference: int) → float
```

Read a double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_ldouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_lfloat(reference: int) → float
```

Read a float from input register memory.

Parameters:
reference – the reference to read from
Returns:

float value read from `reference`

```
read_input_register_lfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_nibble(reference: int) → int
```

Read a nibble from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint16(reference: int) → int
```

Read a signed 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint32(reference: int) → int
```

Read a signed 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint64(reference: int) → int
```

Read a signed 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint8(reference: int) → int
```

Read a signed 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint2143(reference: int) → int
```

Read a signed 2143-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint21436587(reference: int) → int
```

Read a signed 21436587-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 21436587-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:

list of int values read from `reference`

```
read_input_register_sint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 2143-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint3412(reference: int) → int
```

Read a signed 3412-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 3412-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint78563412(reference: int) → int
```

Read a signed 78563412-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 78563412-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint16(reference: int) → int
```

Read a signed 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint32(reference: int) → int
```

Read a signed 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint64(reference: int) → int
```

Read a signed 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint8(reference: int) → int
```

Read a signed 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_string(reference: int, length: int) → bytes
```

Read a string from input register memory.

Parameters:

- **reference** – the reference to read from

- **length** – the length of the value

Returns:
bytes value read from `reference`

```
read_input_register_string_list(reference: int, quantity: int, length: int) →
List[bytes]
```

Read a list of strings from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of bytes values read from `reference`

```
read_input_register_ubint16(reference: int) → int
```

Read an unsigned 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint32(reference: int) → int
```

Read an unsigned 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint64(reference: int) → int
```

Read an unsigned 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint8(reference: int) → int
```

Read an unsigned 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint2143(reference: int) → int
```

Read an unsigned 2143-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint21436587(reference: int) → int
```

Read an unsigned 21436587-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 21436587-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 2143-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint3412(reference: int) → int
```

Read an unsigned 3412-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 3412-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint78563412(reference: int) → int
```

Read an unsigned 78563412-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 78563412-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint16(reference: int) → int
```

Read an unsigned 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint32(reference: int) → int
```

Read an unsigned 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint64(reference: int) → int
```

Read an unsigned 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint8(reference: int) → int
```

Read an unsigned 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_multiple_coils(reference: int, quantity: int) → List[int]
```

Read multiple coils using Modbus function code 1.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of coils to be read.

Returns:
a list of coil states where each element is `1` if the corresponding coil is set and `0` else.

```
read_multiple_discrete_inputs(reference: int, quantity: int) → List[int]
```

Read multiple discrete inputs using Modbus function code 2.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of discrete inputs to be read.

Returns:
a list of discrete inputs where each element is `1` if the corresponding discrete input is set and `0` else.

```
read_multiple_holding_registers(reference: int, quantity: int) → List[int]
```

Read multiple holding registers using Modbus function code 3.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of registers to be read.

Returns:
the holding register values

```
read_multiple_input_registers(reference: int, quantity: int) → List[int]
```

Read multiple input registers using Modbus function code 4.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of registers to be read.

Returns:
the input register values

```
read_write_multiple_holding_registers(read_reference: int, read_quantity: int,
write_reference: int, write_values: List[int]) → List[int]
```

Read/Write multiple holding registers using Modbus function code 23.

Parameters:

- **read_reference** – the register reference to read from.
- **read_quantity** – the number of registers to read.
- **write_reference** – the register reference to to write to.
- **write_values** – the values to be written.

Returns:
the read registers

```
reconnect() → None
```

Reconnect socket.

```
write(adu: SerialRTUModbusRequest | SerialASCIIModbusRequest | TCPModbusRequest,
auto_length: bool = True) → None
```

Write `adu` encoded using the interface. The transaction identifier is set automatically. The unit identifier is put into the adu automatically, too.

Parameters:

- **adu** – a serializable adu
- **auto_length=True** – if set to `True` the length is calculated automatically

```
write_coil(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a single coil using Modbus function code 5.

Parameters:

- **reference** – the register reference.
- **value** – the value to be written.

```
write_coil_bitfield(reference: int, value: int, length: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_coil_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_coil_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct] |
Type[ByteType]) → SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write data to coils using Modbus function code 15.

Parameters:

- **reference** – the coil reference.
- **data** – the type or instance or the decoder for the data

```
write_coil_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_coil_flag_list(reference: int, values: List[bool]) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_coil_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_coil_nibble_list(reference: int, values: List[int]) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_extended_memory(memory_number: int, record_number: int, records: List[int]) → None
```

Write extended memory using Modbus function code 21.

Parameters:

- **memory_number** – the memory number (0x0001 to 0xffff)
- **record_number** – the record to write to
- **records** – the records to be written

```
write_holding_register(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write single holding register using Modbus function code 6.

Parameters:

- **reference** – the register reference.
- **value** – the value to be written into the corresponding register.

```
write_holding_register_bdouble(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_bdouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_bfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_bfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_bitfield(reference: int, value: int, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_holding_register_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_holding_register_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → SerialRTUModbusResponse | SerialASCIIModbusResponse |
TCPModbusResponse
```

Write data to holding registers using Modbus function code 16.

Parameters:

- **reference** – the register reference.
- **data** – the type or instance or the decoder for the data

```
write_holding_register_double21436587(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 21436587-endian double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_double21436587_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 21436587-endian doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_double78563412(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 78563412-endian double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_double78563412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 78563412-endian doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_holding_register_flag_list(reference: int, values: List[bool]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_holding_register_float2143(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 2143-endian float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_float2143_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 2143-endian floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_float3412(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 3412-endian float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_float3412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 3412-endian floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_ldouble(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_ldouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_lfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_lfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_nibble_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 2143-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 21436587-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 21436587-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 2143-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 3412-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 3412-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 78563412-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 78563412-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_string(reference: int, value: bytes, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a string to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bytes value to be written
- **length** – the length of the value

```
write_holding_register_string_list(reference: int, values: List[bytes], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of strings to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bytes values to be written
- **length** – the length of the value

```
write_holding_register_ubint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 2143-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 21436587-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 21436587-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 2143-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 3412-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 3412-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 78563412-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 78563412-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_multiple_coils(reference: int, values: List[int]) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write multiple coils using Modbus function code 15.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

```
write_multiple_holding_registers(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write multiple holding registers using Modbus function code 16.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

UDP Client

```
class htf.modbus.ModbusUDPClient(address: str, port: int = 502, unit_identifier: int = 0,
timeout: int | float = 1.0, retries: int | None = None, references_start_at_one: bool = True,
transaction_identifier: int = 0, request_parser: Type[SerialRTUModbusRequest] |
Type[SerialASCIIModbusRequest] | Type[TCPModbusRequest] = <class
'htf.modbus.protocol.TCPModbusRequest'>, response_parser: Type[SerialRTUModbusResponse] |
Type[SerialASCIIModbusResponse] | Type[TCPModbusResponse] = <class
'htf.modbus.protocol.TCPModbusResponse'>, debuglevel: int | None = None)
```

Parameters:

- **address** – the ip address to connect to
- **port** – the port to be used
- **unit_identifier** – the unit identifier for Modbus TCP
- **timeout** – the timeout in seconds
- **retries=None** – the number of retries until an exception is raised
- **references_start_at_one=True** – if set to `True` all references start at `1` else `0`
- **transaction_identifier** – the initial transaction identifier
- **request_parser** – a parser for requests
- **response_parser** – a parser for responses
- **debuglevel** – the debuglevel (`None` disables debug, `1` prints requests and responses and `2` prints introspection)

```
build_request() → SerialRTUModbusRequest | SerialASCIIModbusRequest | TCPModbusRequest
```

Build and return an instance of the desired request parser.

Returns:
request parser

```
build_response() → SerialRTUModbusResponse | SerialASCIIModbusResponse |
TCPModbusResponse
```

Build and return an instance of the desired response parser.

Returns:
response parser

```
close() → None
```

Close the interface.

```
get_device_identification() → Dict[int, bytes]
```

Query and return the device identification using Modbus function code 43.14.

Returns:
containing key values pairs with the device identifiers

```
get_fifo_queue_content(address: int) → List[int]
```

Query and return the fifo content of `address` using Modbus function code 24.

Parameters:
address – the fifo queue pointer address
Returns:
list of content from the fifo queue at `address`

```
get_transaction_identifier() → int
```

Create and return a new transaction identifer. Is thread-safe.

Returns:
the next transaction identifier

```
mask_holding_register(reference: int, and_mask: int, or_mask: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Mask write single holding register using Modbus function code 22.

Parameters:

- **reference** – the register reference

- **and_mask** – the and mask
- **or_mask** – the or mask

```
mask_multiple_holding_registers(reference: int, quantity: int, and_mask: int, or_mask: int) → None
```

Mask write multiple holding registers using Modbus function code 16.

Parameters:

- **reference** – the register reference
- **quantity** – the number of registers to be masked
- **and_mask** – the and mask
- **or_mask** – the or mask

```
query(adu: SerialRTUModbusRequest | SerialASCIIModbusRequest | TCPModbusRequest) → SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Query `adu` using the interface and return the decoded response.

Parameters:
adu – a serializable adu
Returns:
the decoded response if no exception occurred
Return type:
adu
Raises:
ModbusException – in case of an exception response

```
read() → SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Read a message from the interface and decode it.

Returns:
the decoded adu as is
Return type:
adu
Raises:
Exception if no answer was received –

```
read_coil(reference: int) → int
```

Read a single coil using Modbus function code 1.

Parameters:
reference – the register reference.
Returns:

`1` if the coil is set and `0` else.

```
read_coil_bitfield(reference: int, length: int) → int
```

Read a bitfield from coil memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_coil_bitfield_list(reference: int, quantity: int, length: int) → List[int]
```

Read a list of bitfields from coil memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_coil_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct] |
Type[ByteType]) → ByteStruct | ByteType
```

Read data from coils using Modbus function code 1.

Parameters:

- **reference** – the coil reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_coil_flag(reference: int) → bool
```

Read a bit from coil memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_coil_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from coil memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_coil_nibble(reference: int) → int
```

Read a nibble from coil memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_coil_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from coil memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_discrete_input(reference: int) → int
```

Read single discrete input using Modbus function code 2.

Parameters:
reference – the register reference.
Returns:
`1` if the discrete input is set and `0` else.

```
read_discrete_input_bitfield(reference: int, length: int) → int
```

Read a bitfield from discrete input memory.

Parameters:

- **reference** – the reference to read from

- **length** – the length of the value

Returns:
int value read from `reference`

```
read_discrete_input_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_discrete_input_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct]
| Type[ByteType]) → ByteStruct | ByteType
```

Read data from discrete inputs using Modbus function code 2.

Parameters:

- **reference** – the discrete input reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_discrete_input_flag(reference: int) → bool
```

Read a bit from discrete input memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_discrete_input_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_discrete_input_nibble(reference: int) → int
```

Read a nibble from discrete input memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_discrete_input_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_extended_memory(memory_number: int, record_number: int, record_length: int) →
List[int]
```

Query and return extended memory from device using Modbus function code 20.

Parameters:

- **memory_number** – the memory number (0x0001 to 0xffff)
- **record_number** – the record to start reading from
- **record_length** – the length of records

Returns:
the read records

```
read_holding_register(reference: int) → int
```

Read a single holding register using Modbus function code 3.

Parameters:
reference – the register reference.
Returns:
the holding register value

```
read_holding_register_bdouble(reference: int) → float
```

Read a double from holding register memory.

Parameters:

reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_bdouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_bfloat(reference: int) → float
```

Read a float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_bfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_bitfield(reference: int, length: int) → int
```

Read a bitfield from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_holding_register_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → ByteStruct | ByteType
```

Read data from holding registers using Modbus function code 3.

Parameters:

- **reference** – the register reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_holding_register_double21436587(reference: int) → float
```

Read a 21436587-endian double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_double21436587_list(reference: int, quantity: int) → List[float]
```

Read a list of 21436587-endian doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_double78563412(reference: int) → float
```

Read a 78563412-endian double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_double78563412_list(reference: int, quantity: int) → List[float]
```

Read a list of 78563412-endian doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_flag(reference: int) → bool
```

Read a bit from holding register memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_holding_register_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_holding_register_float2143(reference: int) → float
```

Read a 2143-endian float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_float2143_list(reference: int, quantity: int) → List[float]
```

Read a list of 2143-endian floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_float3412(reference: int) → float
```

Read a 3412-endian float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_float3412_list(reference: int, quantity: int) → List[float]
```

Read a list of 3412-endian floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_ldouble(reference: int) → float
```

Read a double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_ldouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from holding register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_lfloat(reference: int) → float
```

Read a float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_lfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_nibble(reference: int) → int
```

Read a nibble from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint16(reference: int) → int
```

Read a signed 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint32(reference: int) → int
```

Read a signed 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint64(reference: int) → int
```

Read a signed 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint8(reference: int) → int
```

Read a signed 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint2143(reference: int) → int
```

Read a signed 2143-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint21436587(reference: int) → int
```

Read a signed 21436587-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:

int value read from `reference`

```
read_holding_register_sint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 21436587-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 2143-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint3412(reference: int) → int
```

Read a signed 3412-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 3412-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint78563412(reference: int) → int
```

Read a signed 78563412-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 78563412-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint16(reference: int) → int
```

Read a signed 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint32(reference: int) → int
```

Read a signed 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint64(reference: int) → int
```

Read a signed 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint8(reference: int) → int
```

Read a signed 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_string(reference: int, length: int) → bytes
```

Read a string from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
bytes value read from `reference`

```
read_holding_register_string_list(reference: int, quantity: int, length: int) →
List[bytes]
```

Read a list of strings from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of bytes values read from `reference`

```
read_holding_register_ubint16(reference: int) → int
```

Read an unsigned 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint32(reference: int) → int
```

Read an unsigned 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint64(reference: int) → int
```

Read an unsigned 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint8(reference: int) → int
```

Read an unsigned 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint2143(reference: int) → int
```

Read an unsigned 2143-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint21436587(reference: int) → int
```

Read an unsigned 21436587-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 21436587-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 2143-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint3412(reference: int) → int
```

Read an unsigned 3412-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 3412-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint78563412(reference: int) → int
```

Read an unsigned 78563412-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 78563412-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint16(reference: int) → int
```

Read an unsigned 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:

int value read from `reference`

```
read_holding_register_ulint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint32(reference: int) → int
```

Read an unsigned 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint64(reference: int) → int
```

Read an unsigned 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint8(reference: int) → int
```

Read an unsigned 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register(reference: int) → int
```

Read a single input register using Modbus function code 4.

Parameters:
reference – the register reference.
Returns:
the input register value

```
read_input_register_bdouble(reference: int) → float
```

Read a double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_bdouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_bfloat(reference: int) → float
```

Read a float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_bfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_bitfield(reference: int, length: int) → int
```

Read a bitfield from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_input_register_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct]
| Type[ByteType]) → ByteStruct | ByteType
```

Read data from input registers using Modbus function code 4.

Parameters:

- **reference** – the register reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_input_register_double21436587(reference: int) → float
```

Read a 21436587-endian double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_double21436587_list(reference: int, quantity: int) → List[float]
```

Read a list of 21436587-endian doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_double78563412(reference: int) → float
```

Read a 78563412-endian double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_double78563412_list(reference: int, quantity: int) → List[float]
```

Read a list of 78563412-endian doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_flag(reference: int) → bool
```

Read a bit from input register memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_input_register_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_input_register_float2143(reference: int) → float
```

Read a 2143-endian float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_float2143_list(reference: int, quantity: int) → List[float]
```

Read a list of 2143-endian floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_float3412(reference: int) → float
```

Read a 3412-endian float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_float3412_list(reference: int, quantity: int) → List[float]
```

Read a list of 3412-endian floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_ldouble(reference: int) → float
```

Read a double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_ldouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_lfloat(reference: int) → float
```

Read a float from input register memory.

Parameters:
reference – the reference to read from
Returns:

float value read from `reference`

```
read_input_register_lfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_nibble(reference: int) → int
```

Read a nibble from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint16(reference: int) → int
```

Read a signed 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint32(reference: int) → int
```

Read a signed 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint64(reference: int) → int
```

Read a signed 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint8(reference: int) → int
```

Read a signed 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint2143(reference: int) → int
```

Read a signed 2143-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint21436587(reference: int) → int
```

Read a signed 21436587-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 21436587-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:

list of int values read from `reference`

```
read_input_register_sint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 2143-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint3412(reference: int) → int
```

Read a signed 3412-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 3412-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint78563412(reference: int) → int
```

Read a signed 78563412-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 78563412-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint16(reference: int) → int
```

Read a signed 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint32(reference: int) → int
```

Read a signed 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint64(reference: int) → int
```

Read a signed 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint8(reference: int) → int
```

Read a signed 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_string(reference: int, length: int) → bytes
```

Read a string from input register memory.

Parameters:

- **reference** – the reference to read from

- **length** – the length of the value

Returns:
bytes value read from `reference`

```
read_input_register_string_list(reference: int, quantity: int, length: int) →
List[bytes]
```

Read a list of strings from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of bytes values read from `reference`

```
read_input_register_ubint16(reference: int) → int
```

Read an unsigned 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint32(reference: int) → int
```

Read an unsigned 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint64(reference: int) → int
```

Read an unsigned 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint8(reference: int) → int
```

Read an unsigned 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint2143(reference: int) → int
```

Read an unsigned 2143-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint21436587(reference: int) → int
```

Read an unsigned 21436587-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 21436587-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 2143-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint3412(reference: int) → int
```

Read an unsigned 3412-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 3412-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint78563412(reference: int) → int
```

Read an unsigned 78563412-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 78563412-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint16(reference: int) → int
```

Read an unsigned 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint32(reference: int) → int
```

Read an unsigned 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint64(reference: int) → int
```

Read an unsigned 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint8(reference: int) → int
```

Read an unsigned 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_multiple_coils(reference: int, quantity: int) → List[int]
```

Read multiple coils using Modbus function code 1.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of coils to be read.

Returns:
a list of coil states where each element is `1` if the corresponding coil is set and `0` else.

```
read_multiple_discrete_inputs(reference: int, quantity: int) → List[int]
```

Read multiple discrete inputs using Modbus function code 2.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of discrete inputs to be read.

Returns:
a list of discrete inputs where each element is `1` if the corresponding discrete input is set and `0` else.

```
read_multiple_holding_registers(reference: int, quantity: int) → List[int]
```

Read multiple holding registers using Modbus function code 3.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of registers to be read.

Returns:
the holding register values

```
read_multiple_input_registers(reference: int, quantity: int) → List[int]
```

Read multiple input registers using Modbus function code 4.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of registers to be read.

Returns:
the input register values

```
read_write_multiple_holding_registers(read_reference: int, read_quantity: int,
write_reference: int, write_values: List[int]) → List[int]
```

Read/Write multiple holding registers using Modbus function code 23.

Parameters:

- **read_reference** – the register reference to read from.
- **read_quantity** – the number of registers to read.
- **write_reference** – the register reference to to write to.
- **write_values** – the values to be written.

Returns:
the read registers

```
reconnect() → None
```

Reconnect socket.

```
write(adu: SerialRTUModbusRequest | SerialASCIIModbusRequest | TCPModbusRequest,
auto_length: bool = True) → None
```

Write `adu` encoded using the interface. The transaction identifier is set automatically. The unit identifier is put into the adu automatically, too.

Parameters:

- **adu** – a serializable adu
- **auto_length=True** – if set to `True` the length is calculated automatically

```
write_coil(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a single coil using Modbus function code 5.

Parameters:

- **reference** – the register reference.
- **value** – the value to be written.

```
write_coil_bitfield(reference: int, value: int, length: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_coil_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_coil_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct] |
Type[ByteType]) → SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write data to coils using Modbus function code 15.

Parameters:

- **reference** – the coil reference.
- **data** – the type or instance or the decoder for the data

```
write_coil_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_coil_flag_list(reference: int, values: List[bool]) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_coil_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_coil_nibble_list(reference: int, values: List[int]) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_extended_memory(memory_number: int, record_number: int, records: List[int]) → None
```

Write extended memory using Modbus function code 21.

Parameters:

- **memory_number** – the memory number (0x0001 to 0xffff)
- **record_number** – the record to write to
- **records** – the records to be written

```
write_holding_register(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write single holding register using Modbus function code 6.

Parameters:

- **reference** – the register reference.
- **value** – the value to be written into the corresponding register.

```
write_holding_register_bdouble(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_bdouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_bfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_bfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_bitfield(reference: int, value: int, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_holding_register_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_holding_register_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → SerialRTUModbusResponse | SerialASCIIModbusResponse |
TCPModbusResponse
```

Write data to holding registers using Modbus function code 16.

Parameters:

- **reference** – the register reference.
- **data** – the type or instance or the decoder for the data

```
write_holding_register_double21436587(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 21436587-endian double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_double21436587_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 21436587-endian doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_double78563412(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 78563412-endian double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_double78563412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 78563412-endian doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_holding_register_flag_list(reference: int, values: List[bool]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_holding_register_float2143(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 2143-endian float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_float2143_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 2143-endian floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_float3412(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 3412-endian float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_float3412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 3412-endian floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_ldouble(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_ldouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_lfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_lfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_nibble_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 2143-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 21436587-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 21436587-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 2143-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 3412-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 3412-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 78563412-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 78563412-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_string(reference: int, value: bytes, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a string to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bytes value to be written
- **length** – the length of the value

```
write_holding_register_string_list(reference: int, values: List[bytes], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of strings to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bytes values to be written
- **length** – the length of the value

```
write_holding_register_ubint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 2143-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 21436587-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 21436587-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 2143-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 3412-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 3412-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 78563412-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 78563412-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_multiple_coils(reference: int, values: List[int]) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write multiple coils using Modbus function code 15.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

```
write_multiple_holding_registers(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write multiple holding registers using Modbus function code 16.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

Servers

Servers are used to respond to queries initiated by clients. Servers are used by devices. Users can add own servers using own interfaces.

Base Server

```
class htf.modbus.ModbusBaseServer
```

Modbus Base Server is an abstract base class.

```
clear_counters() → None
```

Clear all counters.

```
clear_diagnostics() → None
```

Clear diagnostics.

```
close() → None
```

Close interface and stop the server.

```
handle_request(data: bytes) → None
```

Request handler.

Raises:
Exception – abstract base class has no implementation.

```
set_listen_only_mode(listen_only_mode_enabled: bool = True) → None
```

Set listen only mode.

Parameters:
listen_only_mode_enabled – `True` enables the listen only mode. `False` disables it.

```
start() → None
```

Start the server.

Raises:
Exception – abstract base class has no implementation.

```
stop() → None
```

Stop the server.

Raises:
Exception – abstract base class has no implementation.

Serial RTU Server

```
class htf.modbus.ModbusSerialRTUServer(com_port: str, baud: int = 9600, bytesize: int = 8,
parity: str = 'E', stopbits: int = 1, rtscts: bool = False, device_address: int = 1, timeout:
int | float = 1.0, request_parser: ByteStruct | BitStruct | ByteType | BitType = <class
'htf.modbus.protocol.SerialRTUModbusRequest'>, response_parser: ByteStruct | BitStruct |
ByteType | BitType = <class 'htf.modbus.protocol.SerialRTUModbusResponse'>, callback:
Callable | None = None)
```

Parameters:

- **com_port** – the com port to be used
- **baud** – the baud rate
- **bytesize** – number of bits in a byte
- **parity** – serial.PARITY_NONE, serial.PARITY_ODD or serial.PARITY_EVEN
- **stopbits** – number of stopbits (1, 1.5 or 2)
- **rtscts** – if True use flow control
- **device_address** – the device address to be used (Slave ID)

- **timeout** – the timeout in seconds
- **request_parser** – the request parser
- **response_parser** – the response parser
- **callback** – a callback used as a request handler

```
clear_counters() → None
```

Clear all counters.

```
clear_diagnostics() → None
```

Clear diagnostics.

```
close() → None
```

Close interface and stop the server.

```
disable_broken_checksums() → None
```

Disable broken checksums for testing purposes.

```
enable_broken_checksums() → None
```

Enable broken checksums for testing purposes.

```
static get_broadcast_enabled_function_codes() → List[int]
```

Return a list of functions codes that are processed for broadcast requests. By default the function codes `5`, `6`, `15` and `16` are supported. This method can be overwritten easily.

Returns:
a list of int containing the supported function codes

```
handle_request(data: bytes) → None
```

Request handler. A request is handled by calling the callback.

Parameters:
data – a request to be handled

```
set_listen_only_mode(listen_only_mode_enabled: bool = True) → None
```

Set listen only mode.

Parameters:
listen_only_mode_enabled – `True` enables the listen only mode. `False` disables it.

```
set_receive_event_callback(callback: Callable | None) → None
```

Set the callback to emit events.

Parameters:
callback – the callback to be called

```
start() → None
```

Start the server.

```
stop() → None
```

Stop the server.

Serial ASCII Server

```
class htf.modbus.ModbusSerialASCIIServer(com_port: str, baud: int = 9600,
bytesize: int = 8, parity: str = 'E', stopbits: int = 1, rtscts: bool = False,
device_address: int = 1, timeout: int | float = 1.0, request_parser: ByteStruct | BitStruct |
ByteType | BitType = <class 'htf.modbus.protocol.SerialASCIIModbusRequest'>, response_parser:
ByteStruct | BitStruct | ByteType | BitType = <class
'htf.modbus.protocol.SerialASCIIModbusResponse'>, callback: Callable | None = None)
```

Parameters:

- **com_port** – the com port to be used
- **baud** – the baud rate
- **bytesize** – number of bits in a byte
- **parity** – serial.PARITY_NONE, serial.PARITY_ODD or serial.PARITY_EVEN
- **stopbits** – number of stopbits (1, 1.5 or 2)
- **rtscts** – if True use flow control
- **device_address** – the device address to be used (Slave ID)
- **timeout** – the timeout in seconds
- **request_parser** – the request parser
- **response_parser** – the response parser
- **callback** – a callback used as a request handler

```
change_ascii_delimiter(delimiter: bytes) → None
```

Change ASCII delimiter to `ascii_delimiter`.

Parameters:
delimiter – bytes of length 1 representing the new lf character

```
clear_counters() → None
```

Clear all counters.

```
clear_diagnostics() → None
```

Clear diagnostics.

```
close() → None
```

Close interface and stop the server.

```
disable_broken_checksums() → None
```

Disable broken checksums for testing purposes.

```
enable_broken_checksums() → None
```

Enable broken checksums for testing purposes.

```
static get_broadcast_enabled_function_codes() → List[int]
```

Return a list of functions codes that are processed for broadcast requests. By default the function codes `5`, `6`, `15` and `16` are supported. This method can be overwritten easily.

Returns:
a list of int containing the supported function codes

```
handle_request(data: bytes) → None
```

Request handler. A request is handled by calling the callback.

Parameters:
data – a request to be handled

```
set_listen_only_mode(listen_only_mode_enabled: bool = True) → None
```

Set listen only mode.

Parameters:
listen_only_mode_enabled – `True` enables the listen only mode. `False` disables it.

```
set_receive_event_callback(callback: Callable | None) → None
```

Set the callback to emit events.

Parameters:
callback – the callback to be called

```
start() → None
```

Start the server.

```
stop() → None
```

Stop the server.

Device Simulators

Devices are used to simulate Modbus devices. Users can add own devices with own commands easily.

Base Device

```
class htf.modbus.ModbusBaseDevice(server: ModbusBaseServer, memory: ModbusMemory,
debuglevel: int | None = None)
```

Parameters:

- **server** – a server instance to be used
- **memory** – a memory instance to be used
- **debuglevel** – the debuglevel (`None` disables debug, `1` prints requests and responses and `2` prints introspection)

```
close() → None
```

Close the device simulator and the server.

```
create_exception_response(request_pdu: RequestPDU, exception_code: str) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler to response with an exception.

Parameters:

- **request_pdu** – the request pdu
- **exception_code** – the exception code to be sent

Returns:
the response to be sent to the client

```
get_extended_memory(memory_number: int) → Dict[int, List[int]] | None
```

Get extended memory.

Parameters:
memory_number – the memory number (0x0001 to 0xFFFF)
Returns:
the extended memory at `memory_number` as a dict with key record numer and values list of
integers

Return type:
list of int
Raises:
KeyError – if the `memory_number` was not found in extended memory.

```
handle_function_code_1(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 1 ``Read Coils`.``.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_15(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 15 `Write Multiple Coils`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_16(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 16 `Write Multiple Registers`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_2(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 2 `Read Discrete Inputs`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_20(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 20 `Read File Record`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_21(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 21 `Write File Record`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_22(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 22 `Mask Write Register`.

Parameters:
pdu – the request pdu

Returns:
the response to be sent to the client

```
handle_function_code_23(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 23 `Read/Write Multiple Registers`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_24(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 24 `Read FIFO Queue`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_3(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 3 `Read Holding Registers`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_4(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 4 `Read Input Registers`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_43(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Encapsulated Interface Transport.

Calls a handler by mei type with the name `handle_function_code_43_mei_type_<mei type>`. To add more mei types more handlers have to be added.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_43_mei_type_14(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Encapsulated Interface Transport: Read Device Identification. Basic object ids can be read.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_5(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 5 `Write Single Coil`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_6(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 6 `Write Single Register`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_request(adu: SerialRTUModbusRequest | SerialASCIIModbusRequest | TCPModbusRequest)
→ SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for an incoming request.

Parameters:
adu – a request adu
Returns:

the command or exception handler

```
mask_holding_register(reference: int, and_mask: int, or_mask: int) → None
```

Mask write single holding register from device memory.

Parameters:

- **reference** – the register reference
- **and_mask** – the and mask
- **or_mask** – the or mask

```
mask_multiple_holding_registers(reference: int, quantity: int, and_mask: int, or_mask:
int) → None
```

Mask write multiple holding registers from device memory.

Parameters:

- **reference** – the register reference
- **quantity** – the number of registers to be masked
- **and_mask** – the and mask
- **or_mask** – the or mask

```
read_coil(reference: int) → int
```

Read a single coil from device memory.

Parameters:
reference – the register reference.
Returns:
`1` if the coil is set and `0` else.

```
read_coil_bitfield(reference: int, length: int) → int
```

Read a bitfield from coil memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_coil_bitfield_list(reference: int, quantity: int, length: int) → List[int]
```

Read a list of bitfields from coil memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_coil_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct] |
Type[ByteType]) → ByteStruct | ByteType
```

Read data from coils device memory.

Parameters:

- **reference** – the coil reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_coil_flag(reference: int) → bool
```

Read a bit from coil memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_coil_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from coil memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_coil_nibble(reference: int) → int
```

Read a nibble from coil memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_coil_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from coil memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_discrete_input(reference: int) → int
```

Read single discrete input from device memory

Parameters:
reference – the register reference.
Returns:
`1` if the discrete input is set and `0` else.

```
read_discrete_input_bitfield(reference: int, length: int) → int
```

Read a bitfield from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_discrete_input_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_discrete_input_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct]
| Type[ByteType]) → ByteStruct | ByteType
```

Read data from discrete inputs device memory.

Parameters:

- **reference** – the discrete input reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_discrete_input_flag(reference: int) → bool
```

Read a bit from discrete input memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_discrete_input_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_discrete_input_nibble(reference: int) → int
```

Read a nibble from discrete input memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_discrete_input_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register(reference: int) → int
```

Read a single holding register from device memory.

Parameters:
reference – the register reference.
Returns:
the holding register value

```
read_holding_register_bdouble(reference: int) → float
```

Read a double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_bdouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_bfloat(reference: int) → float
```

Read a float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_bfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:

list of float values read from `reference`

```
read_holding_register_bitfield(reference: int, length: int) → int
```

Read a bitfield from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_holding_register_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → ByteStruct | ByteType
```

Read data from holding registers device memory.

Parameters:

- **reference** – the register reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_holding_register_double21436587(reference: int) → float
```

Read a 21436587-endian double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_double21436587_list(reference: int, quantity: int) → List[float]
```

Read a list of 21436587-endian doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_double78563412(reference: int) → float
```

Read a 78563412-endian double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_double78563412_list(reference: int, quantity: int) → List[float]
```

Read a list of 78563412-endian doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_flag(reference: int) → bool
```

Read a bit from holding register memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_holding_register_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from holding register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_holding_register_float2143(reference: int) → float
```

Read a 2143-endian float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_float2143_list(reference: int, quantity: int) → List[float]
```

Read a list of 2143-endian floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_float3412(reference: int) → float
```

Read a 3412-endian float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_float3412_list(reference: int, quantity: int) → List[float]
```

Read a list of 3412-endian floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_ldouble(reference: int) → float
```

Read a double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_ldouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_lfloat(reference: int) → float
```

Read a float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_lfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_nibble(reference: int) → int
```

Read a nibble from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint16(reference: int) → int
```

Read a signed 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint32(reference: int) → int
```

Read a signed 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint64(reference: int) → int
```

Read a signed 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint8(reference: int) → int
```

Read a signed 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint2143(reference: int) → int
```

Read a signed 2143-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint21436587(reference: int) → int
```

Read a signed 21436587-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 21436587-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 2143-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint3412(reference: int) → int
```

Read a signed 3412-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 3412-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint78563412(reference: int) → int
```

Read a signed 78563412-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 78563412-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint16(reference: int) → int
```

Read a signed 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint32(reference: int) → int
```

Read a signed 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint64(reference: int) → int
```

Read a signed 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint8(reference: int) → int
```

Read a signed 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_string(reference: int, length: int) → bytes
```

Read a string from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
bytes value read from `reference`

```
read_holding_register_string_list(reference: int, quantity: int, length: int) →
List[bytes]
```

Read a list of strings from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of bytes values read from `reference`

```
read_holding_register_ubint16(reference: int) → int
```

Read an unsigned 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from

Returns:
int value read from `reference`

```
read_holding_register_ubint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint32(reference: int) → int
```

Read an unsigned 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint64(reference: int) → int
```

Read an unsigned 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint8(reference: int) → int
```

Read an unsigned 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint2143(reference: int) → int
```

Read an unsigned 2143-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint21436587(reference: int) → int
```

Read an unsigned 21436587-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 21436587-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 2143-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint3412(reference: int) → int
```

Read an unsigned 3412-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 3412-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint78563412(reference: int) → int
```

Read an unsigned 78563412-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 78563412-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint16(reference: int) → int
```

Read an unsigned 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint32(reference: int) → int
```

Read an unsigned 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint64(reference: int) → int
```

Read an unsigned 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint8(reference: int) → int
```

Read an unsigned 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register(reference: int) → int
```

Read a single input register from device memory.

Parameters:
reference – the register reference.
Returns:
the input register value

```
read_input_register_bdouble(reference: int) → float
```

Read a double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_bdouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_bfloat(reference: int) → float
```

Read a float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_bfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_bitfield(reference: int, length: int) → int
```

Read a bitfield from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_input_register_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct]
| Type[ByteType]) → ByteStruct | ByteType
```

Read data from input registers from device memory.

Parameters:

- **reference** – the register reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_input_register_double21436587(reference: int) → float
```

Read a 21436587-endian double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_double21436587_list(reference: int, quantity: int) → List[float]
```

Read a list of 21436587-endian doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_double78563412(reference: int) → float
```

Read a 78563412-endian double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_double78563412_list(reference: int, quantity: int) → List[float]
```

Read a list of 78563412-endian doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_flag(reference: int) → bool
```

Read a bit from input register memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_input_register_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_input_register_float2143(reference: int) → float
```

Read a 2143-endian float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_float2143_list(reference: int, quantity: int) → List[float]
```

Read a list of 2143-endian floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_float3412(reference: int) → float
```

Read a 3412-endian float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_float3412_list(reference: int, quantity: int) → List[float]
```

Read a list of 3412-endian floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_ldouble(reference: int) → float
```

Read a double from input register memory.

Parameters:
reference – the reference to read from
Returns:

float value read from `reference`

```
read_input_register_ldouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_lfloat(reference: int) → float
```

Read a float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_lfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_nibble(reference: int) → int
```

Read a nibble from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint16(reference: int) → int
```

Read a signed 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint32(reference: int) → int
```

Read a signed 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint64(reference: int) → int
```

Read a signed 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint8(reference: int) → int
```

Read a signed 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint2143(reference: int) → int
```

Read a signed 2143-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:

int value read from `reference`

```
read_input_register_sint21436587(reference: int) → int
```

Read a signed 21436587-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 21436587-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 2143-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint3412(reference: int) → int
```

Read a signed 3412-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 3412-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint78563412(reference: int) → int
```

Read a signed 78563412-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 78563412-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint16(reference: int) → int
```

Read a signed 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint32(reference: int) → int
```

Read a signed 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint64(reference: int) → int
```

Read a signed 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint8(reference: int) → int
```

Read a signed 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:

int value read from `reference`

```
read_input_register_slint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_string(reference: int, length: int) → bytes
```

Read a string from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
bytes value read from `reference`

```
read_input_register_string_list(reference: int, quantity: int, length: int) →
List[bytes]
```

Read a list of strings from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of bytes values read from `reference`

```
read_input_register_ubint16(reference: int) → int
```

Read an unsigned 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint32(reference: int) → int
```

Read an unsigned 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint64(reference: int) → int
```

Read an unsigned 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint8(reference: int) → int
```

Read an unsigned 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint2143(reference: int) → int
```

Read an unsigned 2143-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint21436587(reference: int) → int
```

Read an unsigned 21436587-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 21436587-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 2143-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint3412(reference: int) → int
```

Read an unsigned 3412-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 3412-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint78563412(reference: int) → int
```

Read an unsigned 78563412-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 78563412-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint16(reference: int) → int
```

Read an unsigned 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint32(reference: int) → int
```

Read an unsigned 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint64(reference: int) → int
```

Read an unsigned 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint8(reference: int) → int
```

Read an unsigned 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_multiple_coils(reference: int, quantity: int) → List[int]
```

Read multiple coils from device memory.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of coils to be read.

Returns:
a list of coil states where each element is `1` if the corresponding coil is set and `0` else.

```
read_multiple_discrete_inputs(reference: int, quantity: int) → List[int]
```

Read multiple discrete inputs from device memory.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of discrete inputs to be read.

Returns:
a list of discrete inputs where each element is `1` if the corresponding discrete input is set and `0` else.

```
read_multiple_holding_registers(reference: int, quantity: int) → List[int]
```

Read multiple holding registers from device memory.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of registers to be read.

Returns:
the holding register values

```
read_multiple_input_registers(reference: int, quantity: int) → List[int]
```

Read multiple input registers from device memory.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of registers to be read.

Returns:
the input register values

```
set_device_identifier(object_id: int | None, value: str | bytes | None) → None
```

Set a device identifier. The objects `"vendor_name"`, `"product_code"`, `"major_minor_version"`, `"vendor_url"`, `"product_name"`, `"model_name"` and `"user_application_name"` are predefined.

Set `value` to `None` to remove an entry.

Entries can be read using Modbus function code 43.14.

Parameters:

- **object_id** – the object identifier
- **value** – the value to be used

```
set_extended_memory(memory_number: int, records: Dict[int, List[int]] | None) → None
```

Set extended memory that can be read with Modbus function code 20 and written with Modbus function code 21.

If `records` is `None` the memory is removed.

Parameters:

- **memory_number** – the memory number (0x0001 to 0xFFFF)
- **records** – the records to be stored as a dict with key record numer and values list of integers

```
set_fifo_queue_content(address: int, content: List[int] | None) → None
```

Set the FIFO queue content.

Parameters:

- **address** – the address
- **content** – a list of integers or `None` to delete the queue contents

```
write_coil(reference: int, value: int) → None
```

Write a single coil to device memory.

Parameters:

- **reference** – the register reference.
- **value** – the value to be written.

```
write_coil_bitfield(reference: int, value: int, length: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_coil_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_coil_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct] |
Type[ByteType]) → None
```

Write data to coils device memory.

Parameters:

- **reference** – the coil reference.
- **data** – the type or instance or the decoder for the data

```
write_coil_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_coil_flag_list(reference: int, values: List[bool]) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_coil_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to coil memory.

Parameters:

- **reference** – the reference to write to

- **value** – the int value to be written

```
write_coil_nibble_list(reference: int, values: List[int]) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_discrete_input(reference: int, value: int) → None
```

Read multiple discrete inputs from device memory

Parameters:

- **reference** – the register reference.
- **value** – the value to be written

Returns:
a list of discrete inputs where each element is `1` if the corresponding discrete input is set and `0` else.

```
write_discrete_input_bitfield(reference: int, value: int, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_discrete_input_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_discrete_input_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → None
```

Write data to discrete input device memory.

Parameters:

- **reference** – the discrete input reference.
- **data** – the type or instance or the decoder for the data

```
write_discrete_input_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_discrete_input_flag_list(reference: int, values: List[bool]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_discrete_input_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_discrete_input_nibble_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register(reference: int, value: int) → None
```

Write single holding register to device memory.

Parameters:

- **reference** – the register reference.
- **value** – the value to be written into the corresponding register.

```
write_holding_register_bdouble(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_bdouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_bfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_bfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_bitfield(reference: int, value: int, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_holding_register_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_holding_register_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → None
```

Write data to holding registers device memory.

Parameters:

- **reference** – the register reference.
- **data** – the type or instance or the decoder for the data

```
write_holding_register_double21436587(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 21436587-endian double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_double21436587_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 21436587-endian doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_double78563412(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 78563412-endian double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_double78563412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 78563412-endian doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_holding_register_flag_list(reference: int, values: List[bool]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_holding_register_float2143(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 2143-endian float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_float2143_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 2143-endian floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_float3412(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 3412-endian float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_float3412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 3412-endian floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_ldouble(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_ldouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_lfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_lfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_nibble_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 2143-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 21436587-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 21436587-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 2143-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 3412-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 3412-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 78563412-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 78563412-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_string(reference: int, value: bytes, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a string to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bytes value to be written
- **length** – the length of the value

```
write_holding_register_string_list(reference: int, values: List[bytes], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of strings to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bytes values to be written
- **length** – the length of the value

```
write_holding_register_ubint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 2143-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 21436587-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 21436587-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 2143-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 3412-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 3412-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 78563412-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 78563412-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register(reference: int, value: int) → None
```

Write single input register to device memory.

Parameters:

- **reference** – the register reference.
- **value** – the value to be written into the corresponding register.

```
write_input_register_bdouble(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_bdouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_bfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_bfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_bitfield(reference: int, value: int, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_input_register_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_input_register_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → None
```

Write data to input registers device memory.

Parameters:

- **reference** – the register reference.
- **data** – the type or instance or the decoder for the data

```
write_input_register_double21436587(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 21436587-endian double to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_double21436587_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 21436587-endian doubles to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_double78563412(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 78563412-endian double to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_double78563412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 78563412-endian doubles to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_input_register_flag_list(reference: int, values: List[bool]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_input_register_float2143(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 2143-endian float to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_float2143_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 2143-endian floats to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_float3412(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 3412-endian float to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_float3412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 3412-endian floats to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_ldouble(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_ldouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_lfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_lfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_nibble_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sbint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sbint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sbint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sbint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sbint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sbint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sbint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sbint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 2143-endian 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 21436587-endian 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 21436587-endian 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 2143-endian 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 3412-endian 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 3412-endian 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 78563412-endian 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 78563412-endian 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_slint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_slint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_slint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_slint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_slint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_slint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_slint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_slint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_string(reference: int, value: bytes, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a string to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bytes value to be written
- **length** – the length of the value

```
write_input_register_string_list(reference: int, values: List[bytes], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of strings to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bytes values to be written
- **length** – the length of the value

```
write_input_register_ubint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ubint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ubint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ubint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ubint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ubint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ubint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ubint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_uint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 2143-endian 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_uint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 21436587-endian 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_uint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 21436587-endian 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_uint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 2143-endian 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_uint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 3412-endian 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_uint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 3412-endian 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_uint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 78563412-endian 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_uint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 78563412-endian 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ulint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ulint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ulint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ulint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ulint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ulint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ulint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ulint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_multiple_coils(reference: int, values: List[int]) → None
```

Write multiple coils to device memory.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

```
write_multiple_discrete_inputs(reference: int, values: List[int]) → None
```

Write multiple discrete inputs to device memory.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

```
write_multiple_holding_registers(reference: int, values: List[int]) → None
```

Write multiple holding registers to device memory.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

```
write_multiple_input_registers(reference: int, values: List[int]) → None
```

Write multiple input registers to device memory.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

Serial RTU Device

```
class htf.modbus.ModbusSerialRTUDevice(com_port: str, baud: int = 9600, bytesize: int = 8,
parity: str = 'E', stopbits: int = 1, rtscts: bool = False, device_address: int = 1,
shared_memory: bool = False, request_parser: Type[SerialRTUModbusRequest] |
Type[SerialASCIIModbusRequest] | Type[TCPModbusRequest] = <class
'htf.modbus.protocol.SerialRTUModbusRequest'>, response_parser: Type[SerialRTUModbusResponse]
| Type[SerialASCIIModbusResponse] | Type[TCPModbusResponse] = <class
'htf.modbus.protocol.SerialRTUModbusResponse'>, debuglevel: int | None = None)
```

Parameters:

- **com_port** – the com port to be used

- **baud** – the baud rate
- **bytesize** – number of bits in a byte
- **parity** – serial.PARITY_NONE, serial.PARITY_ODD or serial.PARITY_EVEN
- **stopbits** – number of stopbits (1, 1.5 or 2)
- **rtscts** – if True use flow control
- **device_address** – the device address to be used (Slave ID)
- **shared_memory** – if set to `True` a single shared memory is used
- **request_parser** – the request parser
- **response_parser** – the response parser
- **debuglevel** – the debuglevel (`None` disables debug, `1` prints requests and responses and `2` prints introspection)

```
add_communication_restart_event() → None
```

Add a communication restart event.

```
add_event(event: int) → None
```

Add an event to event log.

Parameters:
event – the event to be added.

```
add_receive_event(is_communication_error: bool = False, is_character_overrun: bool =
False, is_broadcast: bool = False, is_listen_only_mode: bool = False) → None
```

Add a receive event.

Parameters:

- **is_communication_error** – set to `True` if a communication error occurred
- **is_character_overrun** – set to `True` if a character overrun occurred
- **is_broadcast** – set to `True` if a broadcast message was received
- **is_listen_only_mode** – set to `True` if the server is currently in listen only mode

```
add_send_event(read_exception_sent: bool = False, slave_abort_exeception_sent: bool =
False, slave_busy_exception_sent: bool = False, slave_program_nak_exception_sent: bool =
False, write_timeout_occurred: bool = False) → None
```

Add a send event. The current listen only mode is determined automatically.

Parameters:

- **read_exception_sent** – set to `True` if a read exception sent occurred (exception codes 1-3)
- **slave_abort_exeception_sent** – set to `True` if a slave abort exception sent occurred (execption code 4)

- **slave_busy_exception_sent** – set to `True` if a slave busy exception sent occurred (exception codes 5-6)
- **slave_program_nak_exception_sent** – set to `True` if a slave program NAK exception sent occurred (exception code 7)
- **write_timeout_occurred** – set to `True` if a write timeout occurred

```
add_set_listen_only_mode_event() → None
```

Add a listen only mode event.

```
clear_counters_and_diagnostic_register() → None
```

Clear counters and diagnostic register

```
clear_events() → None
```

Clear event log.

```
clear_overrun_counter_and_flag() → None
```

Clear overrun counter and reset the error flag.

```
close() → None
```

Close the device simulator and the server.

```
create_exception_response(request_pdu: RequestPDU, exception_code: str) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler to response with an exception.

Parameters:

- **request_pdu** – the request pdu
- **exception_code** – the exception code to be sent

Returns:
the response to be sent to the client

```
disable_broken_checksums() → None
```

Disable broken checksums for testing purposes.

```
enable_broken_checksums() → None
```

Enable broken checksums for testing purposes.

```
get_bus_character_overrun_count() → int
```

Get the bus character overrun count.

Returns:
the bus character overrun count

```
get_busy_count() → int
```

Return the current busy count.

Returns:
the busy count

```
get_busy_status() → bool
```

Return the current busy status.

Returns:
`True` if the device is busy else `False`

```
get_diagnostic_register() → bytes
```

Return the diagnostic register

Returns:
the content of the diagnostic register

```
get_exception_status() → int
```

Return the current exception status.

Returns:
the current exception status

```
get_extended_memory(memory_number: int) → Dict[int, List[int]] | None
```

Get extended memory.

Parameters:

memory_number – the memory number (0x0001 to 0xFFFF)
Returns:
the extended memory at `memory_number` as a dict with key record numer and values list of
integers

Return type:
list of int
Raises:
KeyError – if the `memory_number` was not found in extended memory.

```
handle_function_code_1(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 1 ``Read Coils`.``.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_11(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 11 `Get Comm Event Counter (Serial Line only)`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_12(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 12 `Get Comm Event Log (Serial Line only)`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_15(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 15 `Write Multiple Coils`.

Parameters:
pdu – the request pdu
Returns:

the response to be sent to the client

```
handle_function_code_16(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 16 `Write Multiple Registers`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_17(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 17 `Report Slave ID (Serial Line only)`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_2(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 2 `Read Discrete Inputs`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_20(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 20 `Read File Record`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_21(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 21 `Write File Record`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_22(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 22 `Mask Write Register`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_23(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 23 `Read/Write Multiple Registers`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_24(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 24 `Read FIFO Queue`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_3(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 3 `Read Holding Registers`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_4(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 4 `Read Input Registers`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_43(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Encapsulated Interface Transport.

Calls a handler by mei type with the name `handle_function_code_43_mei_type_<mei type>`. To add more mei types more handlers have to be added.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_43_mei_type_14(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Encapsulated Interface Transport: Read Device Identification. Basic object ids can be read.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_5(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 5 `Write Single Coil`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_6(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 6 `Write Single Register`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_7(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 7 `Read Exception Status`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_8(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.x Diagnostics (Serial Line only).

Calls a handler by sub function code like `handle_function_code_8_sub_function_<sub function code>`. To add more sub functions more handlers have to be added.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_8_sub_function_0(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.0 `Diagnostics Send Echo Response`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_8_sub_function_1(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.1 `Diagnostics Restart Communications Option`.

Parameters:
pdu – the request pdu

Returns:
the response to be sent to the client

```
handle_function_code_8_sub_function_10(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.10
`Diagnostics Clear counters and diagnostic register`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_8_sub_function_11(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.11 `Diagnostics Bus message count`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_8_sub_function_12(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.12 `Diagnostics Bus communication error count`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_8_sub_function_13(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.13 `Diagnostics Bus exception error count`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_8_sub_function_14(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.14 `Diagnostics Return slave message count`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_8_sub_function_15(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.15 `Diagnostics Slave No Response Count`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_8_sub_function_16(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.16 `Diagnostics Slave NAK Count`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_8_sub_function_17(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.17 `Diagnostics Slave Busy Count`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_8_sub_function_18(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.18 `Diagnostics Slave Character Overrun Count`.

Parameters:
pdu – the request pdu

Returns:
the response to be sent to the client

```
handle_function_code_8_sub_function_2(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.2 `Diagnostics Return diagnostic register`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_8_sub_function_20(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.20 `Diagnostics`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_8_sub_function_3(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.3 `Diagnostics Change ASCII Input Delimiter`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_8_sub_function_4(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.4 `Diagnostics Force Listen Only Mode`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_request(adu: SerialRTUModbusRequest | SerialASCIIModbusRequest | TCPModbusRequest)
→ SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for an incoming request.

Parameters:
adu – a request adu
Returns:
the command or exception handler

```
mask_holding_register(reference: int, and_mask: int, or_mask: int) → None
```

Mask write single holding register from device memory.

Parameters:

- **reference** – the register reference
- **and_mask** – the and mask
- **or_mask** – the or mask

```
mask_multiple_holding_registers(reference: int, quantity: int, and_mask: int, or_mask:
int) → None
```

Mask write multiple holding registers from device memory.

Parameters:

- **reference** – the register reference
- **quantity** – the number of registers to be masked
- **and_mask** – the and mask
- **or_mask** – the or mask

```
read_coil(reference: int) → int
```

Read a single coil from device memory.

Parameters:
reference – the register reference.
Returns:
`1` if the coil is set and `0` else.

```
read_coil_bitfield(reference: int, length: int) → int
```

Read a bitfield from coil memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_coil_bitfield_list(reference: int, quantity: int, length: int) → List[int]
```

Read a list of bitfields from coil memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_coil_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct] |
Type[ByteType]) → ByteStruct | ByteType
```

Read data from coils device memory.

Parameters:

- **reference** – the coil reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_coil_flag(reference: int) → bool
```

Read a bit from coil memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_coil_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from coil memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_coil_nibble(reference: int) → int
```

Read a nibble from coil memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_coil_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from coil memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_discrete_input(reference: int) → int
```

Read single discrete input from device memory

Parameters:
reference – the register reference.
Returns:
`1` if the discrete input is set and `0` else.

```
read_discrete_input_bitfield(reference: int, length: int) → int
```

Read a bitfield from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_discrete_input_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_discrete_input_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct]
| Type[ByteType]) → ByteStruct | ByteType
```

Read data from discrete inputs device memory.

Parameters:

- **reference** – the discrete input reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_discrete_input_flag(reference: int) → bool
```

Read a bit from discrete input memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_discrete_input_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_discrete_input_nibble(reference: int) → int
```

Read a nibble from discrete input memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_discrete_input_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from discrete input memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register(reference: int) → int
```

Read a single holding register from device memory.

Parameters:
reference – the register reference.
Returns:
the holding register value

```
read_holding_register_bdouble(reference: int) → float
```

Read a double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_bdouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_bfloat(reference: int) → float
```

Read a float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_bfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_bitfield(reference: int, length: int) → int
```

Read a bitfield from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_holding_register_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → ByteStruct | ByteType
```

Read data from holding registers device memory.

Parameters:

- **reference** – the register reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_holding_register_double21436587(reference: int) → float
```

Read a 21436587-endian double from holding register memory.

Parameters:

reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_double21436587_list(reference: int, quantity: int) → List[float]
```

Read a list of 21436587-endian doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_double78563412(reference: int) → float
```

Read a 78563412-endian double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_double78563412_list(reference: int, quantity: int) → List[float]
```

Read a list of 78563412-endian doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_flag(reference: int) → bool
```

Read a bit from holding register memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_holding_register_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_holding_register_float2143(reference: int) → float
```

Read a 2143-endian float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_float2143_list(reference: int, quantity: int) → List[float]
```

Read a list of 2143-endian floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_float3412(reference: int) → float
```

Read a 3412-endian float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_float3412_list(reference: int, quantity: int) → List[float]
```

Read a list of 3412-endian floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_ldouble(reference: int) → float
```

Read a double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_ldouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_lfloat(reference: int) → float
```

Read a float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_lfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_nibble(reference: int) → int
```

Read a nibble from holding register memory.

Parameters:
reference – the reference to read from
Returns:

int value read from `reference`

```
read_holding_register_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint16(reference: int) → int
```

Read a signed 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint32(reference: int) → int
```

Read a signed 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint64(reference: int) → int
```

Read a signed 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint8(reference: int) → int
```

Read a signed 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint2143(reference: int) → int
```

Read a signed 2143-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint21436587(reference: int) → int
```

Read a signed 21436587-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 21436587-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 2143-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint3412(reference: int) → int
```

Read a signed 3412-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:

int value read from `reference`

```
read_holding_register_sint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 3412-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint78563412(reference: int) → int
```

Read a signed 78563412-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 78563412-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint16(reference: int) → int
```

Read a signed 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint32(reference: int) → int
```

Read a signed 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint64(reference: int) → int
```

Read a signed 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint8(reference: int) → int
```

Read a signed 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_string(reference: int, length: int) → bytes
```

Read a string from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
bytes value read from `reference`

```
read_holding_register_string_list(reference: int, quantity: int, length: int) →
List[bytes]
```

Read a list of strings from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of bytes values read from `reference`

```
read_holding_register_ubint16(reference: int) → int
```

Read an unsigned 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint32(reference: int) → int
```

Read an unsigned 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint64(reference: int) → int
```

Read an unsigned 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint8(reference: int) → int
```

Read an unsigned 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint2143(reference: int) → int
```

Read an unsigned 2143-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint21436587(reference: int) → int
```

Read an unsigned 21436587-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 21436587-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 2143-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint3412(reference: int) → int
```

Read an unsigned 3412-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 3412-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint78563412(reference: int) → int
```

Read an unsigned 78563412-endian 64-bit integer from holding register memory.

Parameters:

reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 78563412-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint16(reference: int) → int
```

Read an unsigned 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint32(reference: int) → int
```

Read an unsigned 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint64(reference: int) → int
```

Read an unsigned 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint8(reference: int) → int
```

Read an unsigned 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register(reference: int) → int
```

Read a single input register from device memory.

Parameters:
reference – the register reference.
Returns:
the input register value

```
read_input_register_bdouble(reference: int) → float
```

Read a double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_bdouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_bfloat(reference: int) → float
```

Read a float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_bfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:

list of float values read from `reference`

```
read_input_register_bitfield(reference: int, length: int) → int
```

Read a bitfield from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_input_register_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct]
| Type[ByteType]) → ByteStruct | ByteType
```

Read data from input registers from device memory.

Parameters:

- **reference** – the register reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_input_register_double21436587(reference: int) → float
```

Read a 21436587-endian double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_double21436587_list(reference: int, quantity: int) → List[float]
```

Read a list of 21436587-endian doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_double78563412(reference: int) → float
```

Read a 78563412-endian double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_double78563412_list(reference: int, quantity: int) → List[float]
```

Read a list of 78563412-endian doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_flag(reference: int) → bool
```

Read a bit from input register memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_input_register_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from input register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_input_register_float2143(reference: int) → float
```

Read a 2143-endian float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_float2143_list(reference: int, quantity: int) → List[float]
```

Read a list of 2143-endian floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_float3412(reference: int) → float
```

Read a 3412-endian float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_float3412_list(reference: int, quantity: int) → List[float]
```

Read a list of 3412-endian floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_ldouble(reference: int) → float
```

Read a double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_ldouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_lfloat(reference: int) → float
```

Read a float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_lfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_nibble(reference: int) → int
```

Read a nibble from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint16(reference: int) → int
```

Read a signed 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint32(reference: int) → int
```

Read a signed 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint64(reference: int) → int
```

Read a signed 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint8(reference: int) → int
```

Read a signed 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint2143(reference: int) → int
```

Read a signed 2143-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint21436587(reference: int) → int
```

Read a signed 21436587-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 21436587-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 2143-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint3412(reference: int) → int
```

Read a signed 3412-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 3412-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint78563412(reference: int) → int
```

Read a signed 78563412-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 78563412-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint16(reference: int) → int
```

Read a signed 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint32(reference: int) → int
```

Read a signed 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint64(reference: int) → int
```

Read a signed 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint8(reference: int) → int
```

Read a signed 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_string(reference: int, length: int) → bytes
```

Read a string from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
bytes value read from `reference`

```
read_input_register_string_list(reference: int, quantity: int, length: int) →
List[bytes]
```

Read a list of strings from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of bytes values read from `reference`

```
read_input_register_ubint16(reference: int) → int
```

Read an unsigned 16-bit integer from input register memory.

Parameters:
reference – the reference to read from

Returns:
int value read from `reference`

```
read_input_register_ubint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint32(reference: int) → int
```

Read an unsigned 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint64(reference: int) → int
```

Read an unsigned 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint8(reference: int) → int
```

Read an unsigned 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint2143(reference: int) → int
```

Read an unsigned 2143-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint21436587(reference: int) → int
```

Read an unsigned 21436587-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 21436587-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 2143-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint3412(reference: int) → int
```

Read an unsigned 3412-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 3412-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint78563412(reference: int) → int
```

Read an unsigned 78563412-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 78563412-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint16(reference: int) → int
```

Read an unsigned 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint32(reference: int) → int
```

Read an unsigned 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint64(reference: int) → int
```

Read an unsigned 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint8(reference: int) → int
```

Read an unsigned 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_multiple_coils(reference: int, quantity: int) → List[int]
```

Read multiple coils from device memory.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of coils to be read.

Returns:
a list of coil states where each element is `1` if the corresponding coil is set and `0` else.

```
read_multiple_discrete_inputs(reference: int, quantity: int) → List[int]
```

Read multiple discrete inputs from device memory.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of discrete inputs to be read.

Returns:
a list of discrete inputs where each element is `1` if the corresponding discrete input is set and `0` else.

```
read_multiple_holding_registers(reference: int, quantity: int) → List[int]
```

Read multiple holding registers from device memory.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of registers to be read.

Returns:
the holding register values

```
read_multiple_input_registers(reference: int, quantity: int) → List[int]
```

Read multiple input registers from device memory.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of registers to be read.

Returns:
the input register values

```
send_function_code_8_echo_response(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Generate an echo response using the request `pdu`.

Parameters:
pdu – the request pdu

Returns:
the response to be sent to the client

```
set_bus_character_overrun_count(count: int) → None
```

Set the bus character overrun count to `count`.

Parameters:
count – the bus character overrun count

```
set_bus_communication_error_count(count: int) → None
```

Set the bus communication error count to `count`.

Parameters:
count – the bus communication error count

```
set_bus_exception_error_count(count: int) → None
```

Set the bus exception error count to `count`.

Parameters:
count – the bus exception error count

```
set_bus_message_count(count: int) → None
```

Set the bus message count to `count`.

Parameters:
count – the bus message count

```
set_busy_count(count: int) → None
```

Set the slave busy count to `count`.

Parameters:
count – the slave busy count

```
set_busy_status(busy: bool = True) → None
```

Set busy flag which will be reported in Modbus function 11.

Parameters:
busy – if set to `True` the busy state is set to busy else not busy.

```
set_device_identifier(object_id: int | None, value: str | bytes | None) → None
```

Set a device identifier. The objects `"vendor_name"`, `"product_code"`, `"major_minor_version"`, `"vendor_url"`, `"product_name"`, `"model_name"` and `"user_application_name"` are predefined.

Set `value` to `None` to remove an entry.

Entries can be read using Modbus function code 43.14.

Parameters:

- **object_id** – the object identifier
- **value** – the value to be used

```
set_diagnostic_register(content: bytes) → None
```

Set the diagnostic register to `content`

Parameters:
content – the new content for the diagnostic register

```
set_exception_status(status: int) → None
```

Set exception status to `status`.

Parameters:
status – the new exception status

```
set_extended_memory(memory_number: int, records: Dict[int, List[int]] | None) → None
```

Set extended memory that can be read with Modbus function code 20 and written with Modbus function code 21.

If `records` is `None` the memory is removed.

Parameters:

- **memory_number** – the memory number (0x0001 to 0xFFFF)
- **records** – the records to be stored as a dict with key record numer and values list of integers

```
set_fifo_queue_content(address: int, content: List[int] | None) → None
```

Set the FIFO queue content.

Parameters:

- **address** – the address
- **content** – a list of integers or `None` to delete the queue contents

```
set_listen_only_mode(listen_only_mode_enabled: bool = True) → None
```

Set listen only mode.

Parameters:
listen_only_enabled – `True` enables the listen only mode. `False` disables it.

```
set_slave_message_count(count: int) → None
```

Set the slave message count to `count`.

Parameters:
count – the slave message count

```
set_slave_nak_count(count: int) → None
```

Set the slave nak count to `count`.

Parameters:
count – the slave nak count

```
set_slave_no_response_count(count: int) → None
```

Set the slave no response count to `count`.

Parameters:
count – the slave no response count

```
write_coil(reference: int, value: int) → None
```

Write a single coil to device memory.

Parameters:

- **reference** – the register reference.
- **value** – the value to be written.

```
write_coil_bitfield(reference: int, value: int, length: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

- **length** – the length of the value

```
write_coil_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_coil_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct] |
Type[ByteType]) → None
```

Write data to coils device memory.

Parameters:

- **reference** – the coil reference.
- **data** – the type or instance or the decoder for the data

```
write_coil_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_coil_flag_list(reference: int, values: List[bool]) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_coil_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_coil_nibble_list(reference: int, values: List[int]) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_discrete_input(reference: int, value: int) → None
```

Read multiple discrete inputs from device memory

Parameters:

- **reference** – the register reference.
- **value** – the value to be written

Returns:
a list of discrete inputs where each element is `1` if the corresponding discrete input is set and `0` else.

```
write_discrete_input_bitfield(reference: int, value: int, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_discrete_input_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_discrete_input_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → None
```

Write data to discrete input device memory.

Parameters:

- **reference** – the discrete input reference.
- **data** – the type or instance or the decoder for the data

```
write_discrete_input_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_discrete_input_flag_list(reference: int, values: List[bool]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_discrete_input_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_discrete_input_nibble_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register(reference: int, value: int) → None
```

Write single holding register to device memory.

Parameters:

- **reference** – the register reference.
- **value** – the value to be written into the corresponding register.

```
write_holding_register_bdouble(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_bdouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_bfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_bfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_bitfield(reference: int, value: int, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_holding_register_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_holding_register_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → None
```

Write data to holding registers device memory.

Parameters:

- **reference** – the register reference.
- **data** – the type or instance or the decoder for the data

```
write_holding_register_double21436587(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 21436587-endian double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_double21436587_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 21436587-endian doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_double78563412(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 78563412-endian double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_double78563412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 78563412-endian doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_holding_register_flag_list(reference: int, values: List[bool]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_holding_register_float2143(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 2143-endian float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_float2143_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 2143-endian floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_float3412(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 3412-endian float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_float3412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 3412-endian floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_ldouble(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_ldouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_lfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_lfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_nibble_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 2143-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 21436587-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 21436587-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 2143-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 3412-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 3412-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 78563412-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 78563412-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_string(reference: int, value: bytes, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a string to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bytes value to be written
- **length** – the length of the value

```
write_holding_register_string_list(reference: int, values: List[bytes], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of strings to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bytes values to be written
- **length** – the length of the value

```
write_holding_register_ubint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 2143-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 21436587-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 21436587-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 2143-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 3412-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 3412-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 78563412-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 78563412-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register(reference: int, value: int) → None
```

Write single input register to device memory.

Parameters:

- **reference** – the register reference.
- **value** – the value to be written into the corresponding register.

```
write_input_register_bdouble(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_bdouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_bfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_bfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_bitfield(reference: int, value: int, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_input_register_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_input_register_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → None
```

Write data to input registers device memory.

Parameters:

- **reference** – the register reference.
- **data** – the type or instance or the decoder for the data

```
write_input_register_double21436587(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 21436587-endian double to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_double21436587_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 21436587-endian doubles to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_double78563412(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 78563412-endian double to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_double78563412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 78563412-endian doubles to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_input_register_flag_list(reference: int, values: List[bool]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_input_register_float2143(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 2143-endian float to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_float2143_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 2143-endian floats to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_float3412(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 3412-endian float to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_float3412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 3412-endian floats to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_ldouble(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_ldouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_lfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_lfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_nibble_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sbint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sbint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sbint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sbint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sbint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sbint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sbint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sbint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 2143-endian 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 21436587-endian 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 21436587-endian 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 2143-endian 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 3412-endian 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 3412-endian 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 78563412-endian 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 78563412-endian 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_slint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_slint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_slint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_slint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_slint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_slint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_slint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_slint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_string(reference: int, value: bytes, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a string to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bytes value to be written
- **length** – the length of the value

```
write_input_register_string_list(reference: int, values: List[bytes], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of strings to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bytes values to be written
- **length** – the length of the value

```
write_input_register_ubint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ubint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ubint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ubint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ubint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ubint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ubint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ubint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_uint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 2143-endian 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_uint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 21436587-endian 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_uint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 21436587-endian 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_uint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 2143-endian 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_uint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 3412-endian 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_uint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 3412-endian 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_uint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 78563412-endian 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_uint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 78563412-endian 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ulint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ulint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ulint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ulint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ulint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ulint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ulint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ulint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_multiple_coils(reference: int, values: List[int]) → None
```

Write multiple coils to device memory.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

```
write_multiple_discrete_inputs(reference: int, values: List[int]) → None
```

Write multiple discrete inputs to device memory.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

```
write_multiple_holding_registers(reference: int, values: List[int]) → None
```

Write multiple holding registers to device memory.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

```
write_multiple_input_registers(reference: int, values: List[int]) → None
```

Write multiple input registers to device memory.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

Serial ASCII Device

```
class htf.modbus.ModbusSerialASCIIDevice(com_port: str, baud: int = 9600,
bytesize: int = 8, parity: str = 'E', stopbits: int = 1, rtscts: bool = False,
device_address: int = 1, shared_memory: bool = False, request_parser:
Type[SerialRTUModbusRequest] | Type[SerialASCIIModbusRequest] | Type[TCPModbusRequest] =
<class 'htf.modbus.protocol.SerialASCIIModbusRequest'>, response_parser:
Type[SerialRTUModbusResponse] | Type[SerialASCIIModbusResponse] | Type[TCPModbusResponse] =
<class 'htf.modbus.protocol.SerialASCIIModbusResponse'>, debuglevel: int | None = None)
```

Parameters:

- **com_port** – the com port to be used

- **baud** – the baud rate
- **bytesize** – number of bits in a byte
- **parity** – serial.PARITY_NONE, serial.PARITY_ODD or serial.PARITY_EVEN
- **stopbits** – number of stopbits (1, 1.5 or 2)
- **rtscts** – if True use flow control
- **device_address** – the device address to be used (Slave ID)
- **shared_memory** – if set to `True` a single shared memory is used
- **request_parser** – the request parser
- **response_parser** – the response parser
- **debuglevel** – the debuglevel (`None` disables debug, `1` prints requests and responses and `2` prints introspection)

```
add_communication_restart_event() → None
```

Add a communication restart event.

```
add_event(event: int) → None
```

Add an event to event log.

Parameters:
event – the event to be added.

```
add_receive_event(is_communication_error: bool = False, is_character_overrun: bool =
False, is_broadcast: bool = False, is_listen_only_mode: bool = False) → None
```

Add a receive event.

Parameters:

- **is_communication_error** – set to `True` if a communication error occurred
- **is_character_overrun** – set to `True` if a character overrun occurred
- **is_broadcast** – set to `True` if a broadcast message was received
- **is_listen_only_mode** – set to `True` if the server is currently in listen only mode

```
add_send_event(read_exception_sent: bool = False, slave_abort_exeception_sent: bool =
False, slave_busy_exception_sent: bool = False, slave_program_nak_exception_sent: bool =
False, write_timeout_occurred: bool = False) → None
```

Add a send event. The current listen only mode is determined automatically.

Parameters:

- **read_exception_sent** – set to `True` if a read exception sent occurred (exception codes 1-3)
- **slave_abort_exeception_sent** – set to `True` if a slave abort exception sent occurred (execption code 4)

- **slave_busy_exception_sent** – set to `True` if a slave busy exception sent occurred (exception codes 5-6)
- **slave_program_nak_exception_sent** – set to `True` if a slave program NAK exception sent occurred (exception code 7)
- **write_timeout_occurred** – set to `True` if a write timeout occurred

```
add_set_listen_only_mode_event() → None
```

Add a listen only mode event.

```
change_ascii_delimiter(delimiter: bytes) → None
```

Change ASCII delimiter.

Parameters:
new_lf – the new ASCII delimiter

```
clear_counters_and_diagnostic_register() → None
```

Clear counters and diagnostic register

```
clear_events() → None
```

Clear event log.

```
clear_overrun_counter_and_flag() → None
```

Clear overrun counter and reset the error flag.

```
close() → None
```

Close the device simulator and the server.

```
create_exception_response(request_pdu: RequestPDU, exception_code: str) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler to response with an exception.

Parameters:

- **request_pdu** – the request pdu
- **exception_code** – the exception code to be sent

Returns:
the response to be sent to the client

```
disable_broken_checksums() → None
```

Disable broken checksums for testing purposes.

```
enable_broken_checksums() → None
```

Enable broken checksums for testing purposes.

```
get_bus_character_overrun_count() → int
```

Get the bus character overrun count.

Returns:
the bus character overrun count

```
get_busy_count() → int
```

Return the current busy count.

Returns:
the busy count

```
get_busy_status() → bool
```

Return the current busy status.

Returns:
`True` if the device is busy else `False`

```
get_diagnostic_register() → bytes
```

Return the diagnostic register

Returns:
the content of the diagnostic register

```
get_exception_status() → int
```

Return the current exception status.

Returns:
the current exception status

```
get_extended_memory(memory_number: int) → Dict[int, List[int]] | None
```

Get extended memory.

Parameters:
memory_number – the memory number (0x0001 to 0xFFFF)
Returns:
the extended memory at `memory_number` as a dict with key record numer and values list of
integers

Return type:
list of int
Raises:
KeyError – if the `memory_number` was not found in extended memory.

```
handle_function_code_1(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 1 ``Read Coils``.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_11(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 11 `Get Comm Event Counter (Serial Line only)`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_12(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 12 `Get Comm Event Log (Serial Line only)`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_15(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 15 `Write Multiple Coils`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_16(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 16 `Write Multiple Registers`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_17(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 17 `Report Slave ID (Serial Line only)`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_2(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 2 `Read Discrete Inputs`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_20(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 20 `Read File Record`.

Parameters:
pdu – the request pdu

Returns:
the response to be sent to the client

```
handle_function_code_21(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 21 `Write File Record`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_22(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 22 `Mask Write Register`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_23(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 23 `Read/Write Multiple Registers`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_24(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 24 `Read FIFO Queue`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_3(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 3 `Read Holding Registers`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_4(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 4 `Read Input Registers`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_43(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Encapsulated Interface Transport.

Calls a handler by mei type with the name `handle_function_code_43_mei_type_<mei type>`. To add more mei types more handlers have to be added.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_43_mei_type_14(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Encapsulated Interface Transport: Read Device Identification. Basic object ids can be read.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_5(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 5 `Write Single Coil`.

Parameters:
pdu – the request pdu
Returns:

the response to be sent to the client

```
handle_function_code_6(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 6 `Write Single Register`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_7(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 7 `Read Exception Status`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_8(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.x Diagnostics (Serial Line only).

Calls a handler by sub function code like `handle_function_code_8_sub_function_<sub function code>`. To add more sub functions more handlers have to be added.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_8_sub_function_0(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.0 `Diagnostics Send Echo Response`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_8_sub_function_1(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.1 `Diagnostics Restart Communications Option`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_8_sub_function_10(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.10
`Diagnostics Clear counters and diagnostic register`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_8_sub_function_11(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.11 `Diagnostics Bus message count`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_8_sub_function_12(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.12 `Diagnostics Bus communication error count`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_8_sub_function_13(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.13 `Diagnostics Bus exception error count`.

Parameters:

pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_8_sub_function_14(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.14 `Diagnostics Return slave message count`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_8_sub_function_15(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.15 `Diagnostics Slave No Response Count`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_8_sub_function_16(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.16 `Diagnostics Slave NAK Count`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_8_sub_function_17(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.17 `Diagnostics Slave Busy Count`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_8_sub_function_18(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.18 `Diagnostics Slave Character Overrun Count`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_8_sub_function_2(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.2 `Diagnostics Return diagnostic register`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_8_sub_function_20(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.20 `Diagnostics`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_8_sub_function_3(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.3 `Diagnostics Change ASCII Input Delimiter`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_8_sub_function_4(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 8.4 `Diagnostics Force Listen Only Mode`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_request(adu: SerialRTUModbusRequest | SerialASCIIModbusRequest | TCPModbusRequest)
→ SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for an incoming request.

Parameters:
adu – a request adu
Returns:
the command or exception handler

```
mask_holding_register(reference: int, and_mask: int, or_mask: int) → None
```

Mask write single holding register from device memory.

Parameters:

- **reference** – the register reference
- **and_mask** – the and mask
- **or_mask** – the or mask

```
mask_multiple_holding_registers(reference: int, quantity: int, and_mask: int, or_mask:
int) → None
```

Mask write multiple holding registers from device memory.

Parameters:

- **reference** – the register reference
- **quantity** – the number of registers to be masked
- **and_mask** – the and mask
- **or_mask** – the or mask

```
read_coil(reference: int) → int
```

Read a single coil from device memory.

Parameters:
reference – the register reference.
Returns:
`1` if the coil is set and `0` else.

```
read_coil_bitfield(reference: int, length: int) → int
```

Read a bitfield from coil memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_coil_bitfield_list(reference: int, quantity: int, length: int) → List[int]
```

Read a list of bitfields from coil memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_coil_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct] |
Type[ByteType]) → ByteStruct | ByteType
```

Read data from coils device memory.

Parameters:

- **reference** – the coil reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_coil_flag(reference: int) → bool
```

Read a bit from coil memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_coil_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from coil memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_coil_nibble(reference: int) → int
```

Read a nibble from coil memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_coil_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from coil memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_discrete_input(reference: int) → int
```

Read single discrete input from device memory

Parameters:
reference – the register reference.
Returns:
`1` if the discrete input is set and `0` else.

```
read_discrete_input_bitfield(reference: int, length: int) → int
```

Read a bitfield from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_discrete_input_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_discrete_input_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct]
| Type[ByteType]) → ByteStruct | ByteType
```

Read data from discrete inputs device memory.

Parameters:

- **reference** – the discrete input reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_discrete_input_flag(reference: int) → bool
```

Read a bit from discrete input memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_discrete_input_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_discrete_input_nibble(reference: int) → int
```

Read a nibble from discrete input memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_discrete_input_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register(reference: int) → int
```

Read a single holding register from device memory.

Parameters:
reference – the register reference.
Returns:
the holding register value

```
read_holding_register_bdouble(reference: int) → float
```

Read a double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_bdouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_bfloat(reference: int) → float
```

Read a float from holding register memory.

Parameters:
reference – the reference to read from
Returns:

float value read from `reference`

```
read_holding_register_bfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_bitfield(reference: int, length: int) → int
```

Read a bitfield from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_holding_register_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → ByteStruct | ByteType
```

Read data from holding registers device memory.

Parameters:

- **reference** – the register reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_holding_register_double21436587(reference: int) → float
```

Read a 21436587-endian double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_double21436587_list(reference: int, quantity: int) → List[float]
```

Read a list of 21436587-endian doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_double78563412(reference: int) → float
```

Read a 78563412-endian double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_double78563412_list(reference: int, quantity: int) → List[float]
```

Read a list of 78563412-endian doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_flag(reference: int) → bool
```

Read a bit from holding register memory.

Parameters:
reference – the reference to read from
Returns:

bool value read from `reference`

```
read_holding_register_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_holding_register_float2143(reference: int) → float
```

Read a 2143-endian float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_float2143_list(reference: int, quantity: int) → List[float]
```

Read a list of 2143-endian floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_float3412(reference: int) → float
```

Read a 3412-endian float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_float3412_list(reference: int, quantity: int) → List[float]
```

Read a list of 3412-endian floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_ldouble(reference: int) → float
```

Read a double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_ldouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_lfloat(reference: int) → float
```

Read a float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_lfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_nibble(reference: int) → int
```

Read a nibble from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint16(reference: int) → int
```

Read a signed 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint32(reference: int) → int
```

Read a signed 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:

int value read from `reference`

```
read_holding_register_sbint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint64(reference: int) → int
```

Read a signed 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint8(reference: int) → int
```

Read a signed 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint2143(reference: int) → int
```

Read a signed 2143-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint21436587(reference: int) → int
```

Read a signed 21436587-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 21436587-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 2143-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint3412(reference: int) → int
```

Read a signed 3412-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 3412-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint78563412(reference: int) → int
```

Read a signed 78563412-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 78563412-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint16(reference: int) → int
```

Read a signed 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:

int value read from `reference`

```
read_holding_register_slint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint32(reference: int) → int
```

Read a signed 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint64(reference: int) → int
```

Read a signed 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint8(reference: int) → int
```

Read a signed 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_string(reference: int, length: int) → bytes
```

Read a string from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
bytes value read from `reference`

```
read_holding_register_string_list(reference: int, quantity: int, length: int) →
List[bytes]
```

Read a list of strings from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of bytes values read from `reference`

```
read_holding_register_ubint16(reference: int) → int
```

Read an unsigned 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint32(reference: int) → int
```

Read an unsigned 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint64(reference: int) → int
```

Read an unsigned 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint8(reference: int) → int
```

Read an unsigned 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint2143(reference: int) → int
```

Read an unsigned 2143-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint21436587(reference: int) → int
```

Read an unsigned 21436587-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 21436587-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 2143-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint3412(reference: int) → int
```

Read an unsigned 3412-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 3412-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint78563412(reference: int) → int
```

Read an unsigned 78563412-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 78563412-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint16(reference: int) → int
```

Read an unsigned 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint32(reference: int) → int
```

Read an unsigned 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:

int value read from `reference`

```
read_holding_register_ulint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint64(reference: int) → int
```

Read an unsigned 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint8(reference: int) → int
```

Read an unsigned 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register(reference: int) → int
```

Read a single input register from device memory.

Parameters:
reference – the register reference.
Returns:
the input register value

```
read_input_register_bdouble(reference: int) → float
```

Read a double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_bdouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_bfloat(reference: int) → float
```

Read a float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_bfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_bitfield(reference: int, length: int) → int
```

Read a bitfield from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_input_register_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct]
| Type[ByteType]) → ByteStruct | ByteType
```

Read data from input registers from device memory.

Parameters:

- **reference** – the register reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_input_register_double21436587(reference: int) → float
```

Read a 21436587-endian double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_double21436587_list(reference: int, quantity: int) → List[float]
```

Read a list of 21436587-endian doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_double78563412(reference: int) → float
```

Read a 78563412-endian double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_double78563412_list(reference: int, quantity: int) → List[float]
```

Read a list of 78563412-endian doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_flag(reference: int) → bool
```

Read a bit from input register memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_input_register_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_input_register_float2143(reference: int) → float
```

Read a 2143-endian float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_float2143_list(reference: int, quantity: int) → List[float]
```

Read a list of 2143-endian floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_float3412(reference: int) → float
```

Read a 3412-endian float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_float3412_list(reference: int, quantity: int) → List[float]
```

Read a list of 3412-endian floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_ldouble(reference: int) → float
```

Read a double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_ldouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_lfloat(reference: int) → float
```

Read a float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_lfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_nibble(reference: int) → int
```

Read a nibble from input register memory.

Parameters:
reference – the reference to read from
Returns:

int value read from `reference`

```
read_input_register_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint16(reference: int) → int
```

Read a signed 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint32(reference: int) → int
```

Read a signed 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint64(reference: int) → int
```

Read a signed 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint8(reference: int) → int
```

Read a signed 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint2143(reference: int) → int
```

Read a signed 2143-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint21436587(reference: int) → int
```

Read a signed 21436587-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 21436587-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 2143-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint3412(reference: int) → int
```

Read a signed 3412-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:

int value read from `reference`

```
read_input_register_sint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 3412-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint78563412(reference: int) → int
```

Read a signed 78563412-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 78563412-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint16(reference: int) → int
```

Read a signed 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint32(reference: int) → int
```

Read a signed 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint64(reference: int) → int
```

Read a signed 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint8(reference: int) → int
```

Read a signed 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_string(reference: int, length: int) → bytes
```

Read a string from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
bytes value read from `reference`

```
read_input_register_string_list(reference: int, quantity: int, length: int) →
List[bytes]
```

Read a list of strings from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of bytes values read from `reference`

```
read_input_register_ubint16(reference: int) → int
```

Read an unsigned 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint32(reference: int) → int
```

Read an unsigned 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint64(reference: int) → int
```

Read an unsigned 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint8(reference: int) → int
```

Read an unsigned 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint2143(reference: int) → int
```

Read an unsigned 2143-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint21436587(reference: int) → int
```

Read an unsigned 21436587-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 21436587-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 2143-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint3412(reference: int) → int
```

Read an unsigned 3412-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 3412-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint78563412(reference: int) → int
```

Read an unsigned 78563412-endian 64-bit integer from input register memory.

Parameters:

reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 78563412-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint16(reference: int) → int
```

Read an unsigned 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint32(reference: int) → int
```

Read an unsigned 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint64(reference: int) → int
```

Read an unsigned 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint8(reference: int) → int
```

Read an unsigned 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_multiple_coils(reference: int, quantity: int) → List[int]
```

Read multiple coils from device memory.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of coils to be read.

Returns:
a list of coil states where each element is `1` if the corresponding coil is set and `0` else.

```
read_multiple_discrete_inputs(reference: int, quantity: int) → List[int]
```

Read multiple discrete inputs from device memory.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of discrete inputs to be read.

Returns:
a list of discrete inputs where each element is `1` if the corresponding discrete input is set and `0` else.

```
read_multiple_holding_registers(reference: int, quantity: int) → List[int]
```

Read multiple holding registers from device memory.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of registers to be read.

Returns:
the holding register values

```
read_multiple_input_registers(reference: int, quantity: int) → List[int]
```

Read multiple input registers from device memory.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of registers to be read.

Returns:
the input register values

```
send_function_code_8_echo_response(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Generate an echo response using the request `pdu`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
set_bus_character_overrun_count(count: int) → None
```

Set the bus character overrun count to `count`.

Parameters:
count – the bus character overrun count

```
set_bus_communication_error_count(count: int) → None
```

Set the bus communication error count to `count`.

Parameters:
count – the bus communication error count

```
set_bus_exception_error_count(count: int) → None
```

Set the bus exception error count to `count`.

Parameters:
count – the bus exception error count

```
set_bus_message_count(count: int) → None
```

Set the bus message count to `count`.

Parameters:
count – the bus message count

```
set_busy_count(count: int) → None
```

Set the slave busy count to `count`.

Parameters:
count – the slave busy count

```
set_busy_status(busy: bool = True) → None
```

Set busy flag which will be reported in Modbus function 11.

Parameters:
busy – if set to `True` the busy state is set to busy else not busy.

```
set_device_identifier(object_id: int | None, value: str | bytes | None) → None
```

Set a device identifier. The objects `"vendor_name"`, `"product_code"`, `"major_minor_version"`, `"vendor_url"`, `"product_name"`, `"model_name"` and `"user_application_name"` are predefined.

Set `value` to `None` to remove an entry.

Entries can be read using Modbus function code 43.14.

Parameters:

- **object_id** – the object identifier
- **value** – the value to be used

```
set_diagnostic_register(content: bytes) → None
```

Set the diagnostic register to `content`

Parameters:
content – the new content for the diagnostic register

```
set_exception_status(status: int) → None
```

Set exception status to `status`.

Parameters:
status – the new exception status

```
set_extended_memory(memory_number: int, records: Dict[int, List[int]] | None) → None
```

Set extended memory that can be read with Modbus function code 20 and written with Modbus function code 21.

If `records` is `None` the memory is removed.

Parameters:

- **memory_number** – the memory number (0x0001 to 0xFFFF)
- **records** – the records to be stored as a dict with key record numer and values list of integers

```
set_fifo_queue_content(address: int, content: List[int] | None) → None
```

Set the FIFO queue content.

Parameters:

- **address** – the address
- **content** – a list of integers or `None` to delete the queue contents

```
set_listen_only_mode(listen_only_mode_enabled: bool = True) → None
```

Set listen only mode.

Parameters:
listen_only_enabled – `True` enables the listen only mode. `False` disables it.

```
set_slave_message_count(count: int) → None
```

Set the slave message count to `count`.

Parameters:
count – the slave message count

```
set_slave_nak_count(count: int) → None
```

Set the slave nak count to `count`.

Parameters:
count – the slave nak count

```
set_slave_no_response_count(count: int) → None
```

Set the slave no response count to `count`.

Parameters:
count – the slave no response count

```
write_coil(reference: int, value: int) → None
```

Write a single coil to device memory.

Parameters:

- **reference** – the register reference.
- **value** – the value to be written.

```
write_coil_bitfield(reference: int, value: int, length: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_coil_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_coil_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct] |
Type[ByteType]) → None
```

Write data to coils device memory.

Parameters:

- **reference** – the coil reference.
- **data** – the type or instance or the decoder for the data

```
write_coil_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_coil_flag_list(reference: int, values: List[bool]) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_coil_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_coil_nibble_list(reference: int, values: List[int]) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_discrete_input(reference: int, value: int) → None
```

Read multiple discrete inputs from device memory

Parameters:

- **reference** – the register reference.
- **value** – the value to be written

Returns:
a list of discrete inputs where each element is `1` if the corresponding discrete input is set and `0` else.

```
write_discrete_input_bitfield(reference: int, value: int, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_discrete_input_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_discrete_input_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → None
```

Write data to discrete input device memory.

Parameters:

- **reference** – the discrete input reference.
- **data** – the type or instance or the decoder for the data

```
write_discrete_input_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_discrete_input_flag_list(reference: int, values: List[bool]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_discrete_input_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_discrete_input_nibble_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register(reference: int, value: int) → None
```

Write single holding register to device memory.

Parameters:

- **reference** – the register reference.
- **value** – the value to be written into the corresponding register.

```
write_holding_register_bdouble(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_bdouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_bfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_bfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_bitfield(reference: int, value: int, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_holding_register_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_holding_register_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → None
```

Write data to holding registers device memory.

Parameters:

- **reference** – the register reference.
- **data** – the type or instance or the decoder for the data

```
write_holding_register_double21436587(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 21436587-endian double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_double21436587_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 21436587-endian doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_double78563412(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 78563412-endian double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_double78563412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 78563412-endian doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_holding_register_flag_list(reference: int, values: List[bool]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_holding_register_float2143(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 2143-endian float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_float2143_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 2143-endian floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_float3412(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 3412-endian float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_float3412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 3412-endian floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_ldouble(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_ldouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_lfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_lfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_nibble_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 2143-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 21436587-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 21436587-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 2143-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 3412-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 3412-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 78563412-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 78563412-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_string(reference: int, value: bytes, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a string to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bytes value to be written

- **length** – the length of the value

```
write_holding_register_string_list(reference: int, values: List[bytes], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of strings to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bytes values to be written
- **length** – the length of the value

```
write_holding_register_ubint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 2143-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 21436587-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 21436587-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 2143-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 3412-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 3412-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 78563412-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 78563412-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register(reference: int, value: int) → None
```

Write single input register to device memory.

Parameters:

- **reference** – the register reference.
- **value** – the value to be written into the corresponding register.

```
write_input_register_bdouble(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_bdouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_bfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_bfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_bitfield(reference: int, value: int, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_input_register_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_input_register_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → None
```

Write data to input registers device memory.

Parameters:

- **reference** – the register reference.
- **data** – the type or instance or the decoder for the data

```
write_input_register_double21436587(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 21436587-endian double to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_double21436587_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 21436587-endian doubles to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_double78563412(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 78563412-endian double to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_double78563412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 78563412-endian doubles to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_input_register_flag_list(reference: int, values: List[bool]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_input_register_float2143(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 2143-endian float to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_float2143_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 2143-endian floats to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_float3412(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 3412-endian float to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_float3412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 3412-endian floats to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_ldouble(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_ldouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_lfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_lfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_nibble_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sbint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sbint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sbint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sbint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sbint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sbint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sbint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sbint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 2143-endian 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 21436587-endian 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 21436587-endian 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 2143-endian 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 3412-endian 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 3412-endian 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 78563412-endian 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 78563412-endian 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_slint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_slint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_slint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_slint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_slint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_slint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_slint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_slint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_string(reference: int, value: bytes, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a string to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bytes value to be written

- **length** – the length of the value

```
write_input_register_string_list(reference: int, values: List[bytes], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of strings to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bytes values to be written
- **length** – the length of the value

```
write_input_register_ubint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ubint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ubint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ubint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ubint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ubint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ubint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ubint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_uint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 2143-endian 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_uint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 21436587-endian 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_uint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 21436587-endian 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_uint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 2143-endian 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_uint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 3412-endian 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_uint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 3412-endian 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_uint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 78563412-endian 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_uint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 78563412-endian 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ulint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ulint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ulint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ulint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ulint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ulint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ulint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ulint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_multiple_coils(reference: int, values: List[int]) → None
```

Write multiple coils to device memory.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

```
write_multiple_discrete_inputs(reference: int, values: List[int]) → None
```

Write multiple discrete inputs to device memory.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

```
write_multiple_holding_registers(reference: int, values: List[int]) → None
```

Write multiple holding registers to device memory.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

```
write_multiple_input_registers(reference: int, values: List[int]) → None
```

Write multiple input registers to device memory.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

TCP Device

```
class htf.modbus.ModbusTCPDevice(bind_address: str, port: int = 502, timeout: int | float =
1.0, shared_memory: bool = False, request_parser: Type[SerialRTUModbusRequest] |
Type[SerialASCIIModbusRequest] | Type[TCPModbusRequest] = <class
'htf.modbus.protocol.TCPModbusRequest'>, response_parser: Type[SerialRTUModbusResponse] |
```

```
Type[SerialASCIIModbusResponse] | Type[TCPModbusResponse] = <class
'htf.modbus.protocol.TCPModbusResponse'>, debuglevel: int | None = None)
```

Parameters:

- **bind_address** – the ip-address to listen on
- **port** – the port to listen on
- **timeout** – the timeout in seconds
- **shared_memory** – if set to `True` a single shared memory is used
- **request_parser** – the request parser
- **response_parser** – the response parser
- **debuglevel** – the debuglevel (`None` disables debug, `1` prints requests and responses and `2` prints introspection)

```
close() → None
```

Close the device simulator and the server.

```
create_exception_response(request_pdu: RequestPDU, exception_code: str) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler to response with an exception.

Parameters:

- **request_pdu** – the request pdu
- **exception_code** – the exception code to be sent

Returns:
the response to be sent to the client

```
get_extended_memory(memory_number: int) → Dict[int, List[int]] | None
```

Get extended memory.

Parameters:
memory_number – the memory number (0x0001 to 0xFFFF)
Returns:
the extended memory at `memory_number` as a dict with key record numer and values list of
integers

Return type:
list of int
Raises:
KeyError – if the `memory_number` was not found in extended memory.

```
handle_function_code_1(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 1 ``Read Coils``.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_15(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 15 `Write Multiple Coils`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_16(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 16 `Write Multiple Registers`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_2(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 2 `Read Discrete Inputs`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_20(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 20 `Read File Record`.

Parameters:
pdu – the request pdu

Returns:
the response to be sent to the client

```
handle_function_code_21(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 21 `Write File Record`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_22(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 22 `Mask Write Register`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_23(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 23 `Read/Write Multiple Registers`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_24(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 24 `Read FIFO Queue`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_3(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 3 `Read Holding Registers`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_4(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 4 `Read Input Registers`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_43(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Encapsulated Interface Transport.

Calls a handler by mei type with the name `handle_function_code_43_mei_type_<mei type>`. To add more mei types more handlers have to be added.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_43_mei_type_14(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Encapsulated Interface Transport: Read Device Identification. Basic object ids can be read.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_5(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 5 `Write Single Coil`.

Parameters:
pdu – the request pdu
Returns:

the response to be sent to the client

```
handle_function_code_6(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 6 `Write Single Register`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_request(adu: SerialRTUModbusRequest | SerialASCIIModbusRequest | TCPModbusRequest)
→ SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for an incoming request.

Parameters:
adu – a request adu
Returns:
the command or exception handler

```
mask_holding_register(reference: int, and_mask: int, or_mask: int) → None
```

Mask write single holding register from device memory.

Parameters:

- **reference** – the register reference
- **and_mask** – the and mask
- **or_mask** – the or mask

```
mask_multiple_holding_registers(reference: int, quantity: int, and_mask: int, or_mask:
int) → None
```

Mask write multiple holding registers from device memory.

Parameters:

- **reference** – the register reference
- **quantity** – the number of registers to be masked
- **and_mask** – the and mask
- **or_mask** – the or mask

```
read_coil(reference: int) → int
```

Read a single coil from device memory.

Parameters:
reference – the register reference.
Returns:
`1` if the coil is set and `0` else.

```
read_coil_bitfield(reference: int, length: int) → int
```

Read a bitfield from coil memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_coil_bitfield_list(reference: int, quantity: int, length: int) → List[int]
```

Read a list of bitfields from coil memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_coil_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct] |
Type[ByteType]) → ByteStruct | ByteType
```

Read data from coils device memory.

Parameters:

- **reference** – the coil reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_coil_flag(reference: int) → bool
```

Read a bit from coil memory.

Parameters:
reference – the reference to read from

Returns:
bool value read from `reference`

```
read_coil_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from coil memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_coil_nibble(reference: int) → int
```

Read a nibble from coil memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_coil_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from coil memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_discrete_input(reference: int) → int
```

Read single discrete input from device memory

Parameters:
reference – the register reference.
Returns:
`1` if the discrete input is set and `0` else.

```
read_discrete_input_bitfield(reference: int, length: int) → int
```

Read a bitfield from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_discrete_input_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_discrete_input_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct]
| Type[ByteType]) → ByteStruct | ByteType
```

Read data from discrete inputs device memory.

Parameters:

- **reference** – the discrete input reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_discrete_input_flag(reference: int) → bool
```

Read a bit from discrete input memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_discrete_input_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_discrete_input_nibble(reference: int) → int
```

Read a nibble from discrete input memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_discrete_input_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register(reference: int) → int
```

Read a single holding register from device memory.

Parameters:
reference – the register reference.
Returns:
the holding register value

```
read_holding_register_bdouble(reference: int) → float
```

Read a double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_bdouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_bfloat(reference: int) → float
```

Read a float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_bfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_bitfield(reference: int, length: int) → int
```

Read a bitfield from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_holding_register_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → ByteStruct | ByteType
```

Read data from holding registers device memory.

Parameters:

- **reference** – the register reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_holding_register_double21436587(reference: int) → float
```

Read a 21436587-endian double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_double21436587_list(reference: int, quantity: int) → List[float]
```

Read a list of 21436587-endian doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_double78563412(reference: int) → float
```

Read a 78563412-endian double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_double78563412_list(reference: int, quantity: int) → List[float]
```

Read a list of 78563412-endian doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_flag(reference: int) → bool
```

Read a bit from holding register memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_holding_register_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_holding_register_float2143(reference: int) → float
```

Read a 2143-endian float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_float2143_list(reference: int, quantity: int) → List[float]
```

Read a list of 2143-endian floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_float3412(reference: int) → float
```

Read a 3412-endian float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_float3412_list(reference: int, quantity: int) → List[float]
```

Read a list of 3412-endian floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_ldouble(reference: int) → float
```

Read a double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_ldouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_lfloat(reference: int) → float
```

Read a float from holding register memory.

Parameters:
reference – the reference to read from
Returns:

float value read from `reference`

```
read_holding_register_lfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_nibble(reference: int) → int
```

Read a nibble from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint16(reference: int) → int
```

Read a signed 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint32(reference: int) → int
```

Read a signed 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint64(reference: int) → int
```

Read a signed 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint8(reference: int) → int
```

Read a signed 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint2143(reference: int) → int
```

Read a signed 2143-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint21436587(reference: int) → int
```

Read a signed 21436587-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 21436587-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:

list of int values read from `reference`

```
read_holding_register_sint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 2143-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint3412(reference: int) → int
```

Read a signed 3412-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 3412-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint78563412(reference: int) → int
```

Read a signed 78563412-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 78563412-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint16(reference: int) → int
```

Read a signed 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint32(reference: int) → int
```

Read a signed 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint64(reference: int) → int
```

Read a signed 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint8(reference: int) → int
```

Read a signed 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_string(reference: int, length: int) → bytes
```

Read a string from holding register memory.

Parameters:

- **reference** – the reference to read from

- **length** – the length of the value

Returns:
bytes value read from `reference`

```
read_holding_register_string_list(reference: int, quantity: int, length: int) →
List[bytes]
```

Read a list of strings from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of bytes values read from `reference`

```
read_holding_register_ubint16(reference: int) → int
```

Read an unsigned 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint32(reference: int) → int
```

Read an unsigned 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint64(reference: int) → int
```

Read an unsigned 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint8(reference: int) → int
```

Read an unsigned 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint2143(reference: int) → int
```

Read an unsigned 2143-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint21436587(reference: int) → int
```

Read an unsigned 21436587-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 21436587-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 2143-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint3412(reference: int) → int
```

Read an unsigned 3412-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 3412-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint78563412(reference: int) → int
```

Read an unsigned 78563412-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 78563412-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint16(reference: int) → int
```

Read an unsigned 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint32(reference: int) → int
```

Read an unsigned 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint64(reference: int) → int
```

Read an unsigned 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint8(reference: int) → int
```

Read an unsigned 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register(reference: int) → int
```

Read a single input register from device memory.

Parameters:
reference – the register reference.
Returns:
the input register value

```
read_input_register_bdouble(reference: int) → float
```

Read a double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_bdouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_bfloat(reference: int) → float
```

Read a float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_bfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_bitfield(reference: int, length: int) → int
```

Read a bitfield from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_input_register_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct]
| Type[ByteType]) → ByteStruct | ByteType
```

Read data from input registers from device memory.

Parameters:

- **reference** – the register reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_input_register_double21436587(reference: int) → float
```

Read a 21436587-endian double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_double21436587_list(reference: int, quantity: int) → List[float]
```

Read a list of 21436587-endian doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_double78563412(reference: int) → float
```

Read a 78563412-endian double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_double78563412_list(reference: int, quantity: int) → List[float]
```

Read a list of 78563412-endian doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_flag(reference: int) → bool
```

Read a bit from input register memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_input_register_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_input_register_float2143(reference: int) → float
```

Read a 2143-endian float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_float2143_list(reference: int, quantity: int) → List[float]
```

Read a list of 2143-endian floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_float3412(reference: int) → float
```

Read a 3412-endian float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_float3412_list(reference: int, quantity: int) → List[float]
```

Read a list of 3412-endian floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_ldouble(reference: int) → float
```

Read a double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_ldouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_lfloat(reference: int) → float
```

Read a float from input register memory.

Parameters:
reference – the reference to read from
Returns:

float value read from `reference`

```
read_input_register_lfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_nibble(reference: int) → int
```

Read a nibble from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint16(reference: int) → int
```

Read a signed 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint32(reference: int) → int
```

Read a signed 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint64(reference: int) → int
```

Read a signed 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint8(reference: int) → int
```

Read a signed 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint2143(reference: int) → int
```

Read a signed 2143-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint21436587(reference: int) → int
```

Read a signed 21436587-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 21436587-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:

list of int values read from `reference`

```
read_input_register_sint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 2143-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint3412(reference: int) → int
```

Read a signed 3412-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 3412-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint78563412(reference: int) → int
```

Read a signed 78563412-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 78563412-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint16(reference: int) → int
```

Read a signed 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint32(reference: int) → int
```

Read a signed 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint64(reference: int) → int
```

Read a signed 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint8(reference: int) → int
```

Read a signed 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_string(reference: int, length: int) → bytes
```

Read a string from input register memory.

Parameters:

- **reference** – the reference to read from

- **length** – the length of the value

Returns:
bytes value read from `reference`

```
read_input_register_string_list(reference: int, quantity: int, length: int) →
List[bytes]
```

Read a list of strings from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of bytes values read from `reference`

```
read_input_register_ubint16(reference: int) → int
```

Read an unsigned 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint32(reference: int) → int
```

Read an unsigned 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint64(reference: int) → int
```

Read an unsigned 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint8(reference: int) → int
```

Read an unsigned 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint2143(reference: int) → int
```

Read an unsigned 2143-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint21436587(reference: int) → int
```

Read an unsigned 21436587-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 21436587-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 2143-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint3412(reference: int) → int
```

Read an unsigned 3412-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 3412-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint78563412(reference: int) → int
```

Read an unsigned 78563412-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 78563412-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint16(reference: int) → int
```

Read an unsigned 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint32(reference: int) → int
```

Read an unsigned 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint64(reference: int) → int
```

Read an unsigned 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint8(reference: int) → int
```

Read an unsigned 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_multiple_coils(reference: int, quantity: int) → List[int]
```

Read multiple coils from device memory.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of coils to be read.

Returns:
a list of coil states where each element is `1` if the corresponding coil is set and `0` else.

```
read_multiple_discrete_inputs(reference: int, quantity: int) → List[int]
```

Read multiple discrete inputs from device memory.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of discrete inputs to be read.

Returns:
a list of discrete inputs where each element is `1` if the corresponding discrete input is set and `0` else.

```
read_multiple_holding_registers(reference: int, quantity: int) → List[int]
```

Read multiple holding registers from device memory.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of registers to be read.

Returns:
the holding register values

```
read_multiple_input_registers(reference: int, quantity: int) → List[int]
```

Read multiple input registers from device memory.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of registers to be read.

Returns:
the input register values

```
set_device_identifier(object_id: int | None, value: str | bytes | None) → None
```

Set a device identifier. The objects `"vendor_name"`, `"product_code"`, `"major_minor_version"`, `"vendor_url"`, `"product_name"`, `"model_name"` and `"user_application_name"` are predefined.

Set `value` to `None` to remove an entry.

Entries can be read using Modbus function code 43.14.

Parameters:

- **object_id** – the object identifier
- **value** – the value to be used

```
set_extended_memory(memory_number: int, records: Dict[int, List[int]] | None) → None
```

Set extended memory that can be read with Modbus function code 20 and written with Modbus function code 21.

If `records` is `None` the memory is removed.

Parameters:

- **memory_number** – the memory number (0x0001 to 0xFFFF)
- **records** – the records to be stored as a dict with key record numer and values list of integers

```
set_fifo_queue_content(address: int, content: List[int] | None) → None
```

Set the FIFO queue content.

Parameters:

- **address** – the address
- **content** – a list of integers or `None` to delete the queue contents

```
write_coil(reference: int, value: int) → None
```

Write a single coil to device memory.

Parameters:

- **reference** – the register reference.
- **value** – the value to be written.

```
write_coil_bitfield(reference: int, value: int, length: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_coil_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_coil_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct] |
Type[ByteType]) → None
```

Write data to coils device memory.

Parameters:

- **reference** – the coil reference.

- **data** – the type or instance or the decoder for the data

```
write_coil_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_coil_flag_list(reference: int, values: List[bool]) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_coil_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_coil_nibble_list(reference: int, values: List[int]) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_discrete_input(reference: int, value: int) → None
```

Read multiple discrete inputs from device memory

Parameters:

- **reference** – the register reference.

- **value** – the value to be written

Returns:
a list of discrete inputs where each element is `1` if the corresponding discrete input is set and `0` else.

```
write_discrete_input_bitfield(reference: int, value: int, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_discrete_input_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_discrete_input_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → None
```

Write data to discrete input device memory.

Parameters:

- **reference** – the discrete input reference.
- **data** – the type or instance or the decoder for the data

```
write_discrete_input_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_discrete_input_flag_list(reference: int, values: List[bool]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_discrete_input_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_discrete_input_nibble_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register(reference: int, value: int) → None
```

Write single holding register to device memory.

Parameters:

- **reference** – the register reference.
- **value** – the value to be written into the corresponding register.

```
write_holding_register_bdouble(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_bdouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_bfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_bfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_bitfield(reference: int, value: int, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_holding_register_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to holding register memory.

Parameters:

- **reference** – the reference to write to

- **values** – a list of int values to be written
- **length** – the length of the value

```
write_holding_register_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → None
```

Write data to holding registers device memory.

Parameters:

- **reference** – the register reference.
- **data** – the type or instance or the decoder for the data

```
write_holding_register_double21436587(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 21436587-endian double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_double21436587_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 21436587-endian doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_double78563412(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 78563412-endian double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_double78563412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 78563412-endian doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_holding_register_flag_list(reference: int, values: List[bool]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_holding_register_float2143(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 2143-endian float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_float2143_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 2143-endian floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_float3412(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 3412-endian float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_float3412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 3412-endian floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_ldouble(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_ldouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_lfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_lfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_nibble_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 2143-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 21436587-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 21436587-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 2143-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 3412-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 3412-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 78563412-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 78563412-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_string(reference: int, value: bytes, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a string to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bytes value to be written
- **length** – the length of the value

```
write_holding_register_string_list(reference: int, values: List[bytes], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of strings to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bytes values to be written
- **length** – the length of the value

```
write_holding_register_ubint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 2143-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 21436587-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 21436587-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 2143-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 3412-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 3412-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 78563412-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 78563412-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register(reference: int, value: int) → None
```

Write single input register to device memory.

Parameters:

- **reference** – the register reference.
- **value** – the value to be written into the corresponding register.

```
write_input_register_bdouble(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_bdouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_bfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_bfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_bitfield(reference: int, value: int, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_input_register_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to input register memory.

Parameters:

- **reference** – the reference to write to

- **values** – a list of int values to be written
- **length** – the length of the value

```
write_input_register_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → None
```

Write data to input registers device memory.

Parameters:

- **reference** – the register reference.
- **data** – the type or instance or the decoder for the data

```
write_input_register_double21436587(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 21436587-endian double to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_double21436587_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 21436587-endian doubles to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_double78563412(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 78563412-endian double to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_double78563412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 78563412-endian doubles to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_input_register_flag_list(reference: int, values: List[bool]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_input_register_float2143(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 2143-endian float to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_float2143_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 2143-endian floats to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_float3412(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 3412-endian float to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_float3412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 3412-endian floats to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_ldouble(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_ldouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_lfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_lfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_nibble_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sbint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sbint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sbint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sbint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sbint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sbint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sbint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sbint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 2143-endian 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 21436587-endian 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 21436587-endian 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 2143-endian 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 3412-endian 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 3412-endian 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 78563412-endian 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 78563412-endian 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_slint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_slint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_slint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_slint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_slint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_slint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_slint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_slint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_string(reference: int, value: bytes, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a string to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bytes value to be written
- **length** – the length of the value

```
write_input_register_string_list(reference: int, values: List[bytes], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of strings to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bytes values to be written
- **length** – the length of the value

```
write_input_register_ubint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ubint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ubint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ubint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ubint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ubint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ubint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ubint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_uint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 2143-endian 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_uint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 21436587-endian 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_uint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 21436587-endian 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_uint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 2143-endian 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_uint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 3412-endian 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_uint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 3412-endian 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_uint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 78563412-endian 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_uint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 78563412-endian 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ulint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ulint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ulint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ulint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ulint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ulint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ulint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ulint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_multiple_coils(reference: int, values: List[int]) → None
```

Write multiple coils to device memory.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

```
write_multiple_discrete_inputs(reference: int, values: List[int]) → None
```

Write multiple discrete inputs to device memory.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

```
write_multiple_holding_registers(reference: int, values: List[int]) → None
```

Write multiple holding registers to device memory.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

```
write_multiple_input_registers(reference: int, values: List[int]) → None
```

Write multiple input registers to device memory.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

UDP Device

```
class htf.modbus.ModbusUDPDevice(bind_address: str, port: int = 502, shared_memory: bool =
False, request_parser: Type[SerialRTUModbusRequest] | Type[SerialASCIIModbusRequest] |
Type[TCPModbusRequest] = <class 'htf.modbus.protocol.TCPModbusRequest'>, response_parser:
Type[SerialRTUModbusResponse] | Type[SerialASCIIModbusResponse] | Type[TCPModbusResponse] =
<class 'htf.modbus.protocol.TCPModbusResponse'>, debuglevel: int | None = None)
```

Parameters:

- **bind_address** – the ip-address to listen on
- **port** – the port to listen on
- **shared_memory** – if set to `True` a single shared memory is used
- **request_parser** – the request parser
- **response_parser** – the response parser
- **debuglevel** – the debuglevel (`None` disables debug, `1` prints requests and responses and `2` prints introspection)

```
close() → None
```

Close the device simulator and the server.

```
create_exception_response(request_pdu: RequestPDU, exception_code: str) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler to response with an exception.

Parameters:

- **request_pdu** – the request pdu
- **exception_code** – the exception code to be sent

Returns:
the response to be sent to the client

```
get_extended_memory(memory_number: int) → Dict[int, List[int]] | None
```

Get extended memory.

Parameters:
memory_number – the memory number (0x0001 to 0xFFFF)
Returns:
the extended memory at `memory_number` as a dict with key record numer and values list of integers

Return type:
list of int
Raises:
KeyError – if the `memory_number` was not found in extended memory.

```
handle_function_code_1(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 1 ``Read Coils``.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_15(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 15 `Write Multiple Coils`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_16(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 16 `Write Multiple Registers`.

Parameters:

pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_2(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 2 `Read Discrete Inputs`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_20(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 20 `Read File Record`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_21(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 21 `Write File Record`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_22(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 22 `Mask Write Register`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_23(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 23 `Read/Write Multiple Registers`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_24(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 24 `Read FIFO Queue`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_3(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 3 `Read Holding Registers`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_4(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 4 `Read Input Registers`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_43(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Encapsulated Interface Transport.

Calls a handler by mei type with the name `handle_function_code_43_mei_type_<mei type>`. To add more mei types more handlers have to be added.

Parameters:
pdu – the request pdu
Returns:

the response to be sent to the client

```
handle_function_code_43_mei_type_14(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Encapsulated Interface Transport: Read Device Identification. Basic object ids can be read.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_5(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 5 `Write Single Coil`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_6(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 6 `Write Single Register`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_request(adu: SerialRTUModbusRequest | SerialASCIIModbusRequest | TCPModbusRequest)
→ SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for an incoming request.

Parameters:
adu – a request adu
Returns:
the command or exception handler

```
mask_holding_register(reference: int, and_mask: int, or_mask: int) → None
```

Mask write single holding register from device memory.

Parameters:

- **reference** – the register reference
- **and_mask** – the and mask
- **or_mask** – the or mask

```
mask_multiple_holding_registers(reference: int, quantity: int, and_mask: int, or_mask: int) → None
```

Mask write multiple holding registers from device memory.

Parameters:

- **reference** – the register reference
- **quantity** – the number of registers to be masked
- **and_mask** – the and mask
- **or_mask** – the or mask

```
read_coil(reference: int) → int
```

Read a single coil from device memory.

Parameters:
reference – the register reference.
Returns:
`1` if the coil is set and `0` else.

```
read_coil_bitfield(reference: int, length: int) → int
```

Read a bitfield from coil memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_coil_bitfield_list(reference: int, quantity: int, length: int) → List[int]
```

Read a list of bitfields from coil memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:

list of int values read from `reference`

```
read_coil_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct] |
Type[ByteType]) → ByteStruct | ByteType
```

Read data from coils device memory.

Parameters:

- **reference** – the coil reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_coil_flag(reference: int) → bool
```

Read a bit from coil memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_coil_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from coil memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_coil_nibble(reference: int) → int
```

Read a nibble from coil memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_coil_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from coil memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_discrete_input(reference: int) → int
```

Read single discrete input from device memory

Parameters:
reference – the register reference.
Returns:
`1` if the discrete input is set and `0` else.

```
read_discrete_input_bitfield(reference: int, length: int) → int
```

Read a bitfield from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_discrete_input_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_discrete_input_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct]
| Type[ByteType]) → ByteStruct | ByteType
```

Read data from discrete inputs device memory.

Parameters:

- **reference** – the discrete input reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_discrete_input_flag(reference: int) → bool
```

Read a bit from discrete input memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_discrete_input_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_discrete_input_nibble(reference: int) → int
```

Read a nibble from discrete input memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_discrete_input_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register(reference: int) → int
```

Read a single holding register from device memory.

Parameters:
reference – the register reference.
Returns:
the holding register value

```
read_holding_register_bdouble(reference: int) → float
```

Read a double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_bdouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_bfloat(reference: int) → float
```

Read a float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_bfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_bitfield(reference: int, length: int) → int
```

Read a bitfield from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_holding_register_bitfield_list(reference: int, quantity: int, length: int) → List[int]
```

Read a list of bitfields from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct] | Type[ByteType]) → ByteStruct | ByteType
```

Read data from holding registers device memory.

Parameters:

- **reference** – the register reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_holding_register_double21436587(reference: int) → float
```

Read a 21436587-endian double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_double21436587_list(reference: int, quantity: int) → List[float]
```

Read a list of 21436587-endian doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_double78563412(reference: int) → float
```

Read a 78563412-endian double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_double78563412_list(reference: int, quantity: int) → List[float]
```

Read a list of 78563412-endian doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_flag(reference: int) → bool
```

Read a bit from holding register memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_holding_register_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_holding_register_float2143(reference: int) → float
```

Read a 2143-endian float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_float2143_list(reference: int, quantity: int) → List[float]
```

Read a list of 2143-endian floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_float3412(reference: int) → float
```

Read a 3412-endian float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_float3412_list(reference: int, quantity: int) → List[float]
```

Read a list of 3412-endian floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_ldouble(reference: int) → float
```

Read a double from holding register memory.

Parameters:
reference – the reference to read from
Returns:

float value read from `reference`

```
read_holding_register_ldouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_lfloat(reference: int) → float
```

Read a float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_lfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_nibble(reference: int) → int
```

Read a nibble from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint16(reference: int) → int
```

Read a signed 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint32(reference: int) → int
```

Read a signed 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint64(reference: int) → int
```

Read a signed 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint8(reference: int) → int
```

Read a signed 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint2143(reference: int) → int
```

Read a signed 2143-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:

int value read from `reference`

```
read_holding_register_sint21436587(reference: int) → int
```

Read a signed 21436587-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 21436587-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 2143-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint3412(reference: int) → int
```

Read a signed 3412-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 3412-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint78563412(reference: int) → int
```

Read a signed 78563412-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 78563412-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint16(reference: int) → int
```

Read a signed 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint32(reference: int) → int
```

Read a signed 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint64(reference: int) → int
```

Read a signed 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint8(reference: int) → int
```

Read a signed 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:

int value read from `reference`

```
read_holding_register_slint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_string(reference: int, length: int) → bytes
```

Read a string from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
bytes value read from `reference`

```
read_holding_register_string_list(reference: int, quantity: int, length: int) →
List[bytes]
```

Read a list of strings from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of bytes values read from `reference`

```
read_holding_register_ubint16(reference: int) → int
```

Read an unsigned 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint32(reference: int) → int
```

Read an unsigned 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint64(reference: int) → int
```

Read an unsigned 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint8(reference: int) → int
```

Read an unsigned 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint2143(reference: int) → int
```

Read an unsigned 2143-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint21436587(reference: int) → int
```

Read an unsigned 21436587-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 21436587-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 2143-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint3412(reference: int) → int
```

Read an unsigned 3412-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 3412-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint78563412(reference: int) → int
```

Read an unsigned 78563412-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 78563412-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint16(reference: int) → int
```

Read an unsigned 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint32(reference: int) → int
```

Read an unsigned 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint64(reference: int) → int
```

Read an unsigned 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint8(reference: int) → int
```

Read an unsigned 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register(reference: int) → int
```

Read a single input register from device memory.

Parameters:
reference – the register reference.
Returns:
the input register value

```
read_input_register_bdouble(reference: int) → float
```

Read a double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_bdouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_bfloat(reference: int) → float
```

Read a float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_bfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_bitfield(reference: int, length: int) → int
```

Read a bitfield from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_input_register_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct]
| Type[ByteType]) → ByteStruct | ByteType
```

Read data from input registers from device memory.

Parameters:

- **reference** – the register reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_input_register_double21436587(reference: int) → float
```

Read a 21436587-endian double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_double21436587_list(reference: int, quantity: int) → List[float]
```

Read a list of 21436587-endian doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_double78563412(reference: int) → float
```

Read a 78563412-endian double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_double78563412_list(reference: int, quantity: int) → List[float]
```

Read a list of 78563412-endian doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_flag(reference: int) → bool
```

Read a bit from input register memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_input_register_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_input_register_float2143(reference: int) → float
```

Read a 2143-endian float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_float2143_list(reference: int, quantity: int) → List[float]
```

Read a list of 2143-endian floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_float3412(reference: int) → float
```

Read a 3412-endian float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_float3412_list(reference: int, quantity: int) → List[float]
```

Read a list of 3412-endian floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_ldouble(reference: int) → float
```

Read a double from input register memory.

Parameters:
reference – the reference to read from
Returns:

float value read from `reference`

```
read_input_register_ldouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_lfloat(reference: int) → float
```

Read a float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_lfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_nibble(reference: int) → int
```

Read a nibble from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint16(reference: int) → int
```

Read a signed 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint32(reference: int) → int
```

Read a signed 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint64(reference: int) → int
```

Read a signed 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint8(reference: int) → int
```

Read a signed 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint2143(reference: int) → int
```

Read a signed 2143-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:

int value read from `reference`

```
read_input_register_sint21436587(reference: int) → int
```

Read a signed 21436587-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 21436587-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 2143-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint3412(reference: int) → int
```

Read a signed 3412-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 3412-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint78563412(reference: int) → int
```

Read a signed 78563412-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 78563412-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint16(reference: int) → int
```

Read a signed 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint32(reference: int) → int
```

Read a signed 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint64(reference: int) → int
```

Read a signed 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint8(reference: int) → int
```

Read a signed 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:

int value read from `reference`

```
read_input_register_slint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_string(reference: int, length: int) → bytes
```

Read a string from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
bytes value read from `reference`

```
read_input_register_string_list(reference: int, quantity: int, length: int) →
List[bytes]
```

Read a list of strings from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of bytes values read from `reference`

```
read_input_register_ubint16(reference: int) → int
```

Read an unsigned 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint32(reference: int) → int
```

Read an unsigned 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint64(reference: int) → int
```

Read an unsigned 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint8(reference: int) → int
```

Read an unsigned 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint2143(reference: int) → int
```

Read an unsigned 2143-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint21436587(reference: int) → int
```

Read an unsigned 21436587-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 21436587-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 2143-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint3412(reference: int) → int
```

Read an unsigned 3412-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 3412-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint78563412(reference: int) → int
```

Read an unsigned 78563412-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 78563412-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint16(reference: int) → int
```

Read an unsigned 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint32(reference: int) → int
```

Read an unsigned 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint64(reference: int) → int
```

Read an unsigned 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint8(reference: int) → int
```

Read an unsigned 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_multiple_coils(reference: int, quantity: int) → List[int]
```

Read multiple coils from device memory.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of coils to be read.

Returns:
a list of coil states where each element is `1` if the corresponding coil is set and `0` else.

```
read_multiple_discrete_inputs(reference: int, quantity: int) → List[int]
```

Read multiple discrete inputs from device memory.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of discrete inputs to be read.

Returns:
a list of discrete inputs where each element is `1` if the corresponding discrete input is set and `0` else.

```
read_multiple_holding_registers(reference: int, quantity: int) → List[int]
```

Read multiple holding registers from device memory.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of registers to be read.

Returns:
the holding register values

```
read_multiple_input_registers(reference: int, quantity: int) → List[int]
```

Read multiple input registers from device memory.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of registers to be read.

Returns:
the input register values

```
set_device_identifier(object_id: int | None, value: str | bytes | None) → None
```

Set a device identifier. The objects `"vendor_name"`, `"product_code"`, `"major_minor_version"`, `"vendor_url"`, `"product_name"`, `"model_name"` and `"user_application_name"` are predefined.

Set `value` to `None` to remove an entry.

Entries can be read using Modbus function code 43.14.

Parameters:

- **object_id** – the object identifier
- **value** – the value to be used

```
set_extended_memory(memory_number: int, records: Dict[int, List[int]] | None) → None
```

Set extended memory that can be read with Modbus function code 20 and written with Modbus function code 21.

If `records` is `None` the memory is removed.

Parameters:

- **memory_number** – the memory number (0x0001 to 0xFFFF)
- **records** – the records to be stored as a dict with key record numer and values list of integers

```
set_fifo_queue_content(address: int, content: List[int] | None) → None
```

Set the FIFO queue content.

Parameters:

- **address** – the address
- **content** – a list of integers or `None` to delete the queue contents

```
write_coil(reference: int, value: int) → None
```

Write a single coil to device memory.

Parameters:

- **reference** – the register reference.
- **value** – the value to be written.

```
write_coil_bitfield(reference: int, value: int, length: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_coil_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_coil_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct] |
Type[ByteType]) → None
```

Write data to coils device memory.

Parameters:

- **reference** – the coil reference.
- **data** – the type or instance or the decoder for the data

```
write_coil_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_coil_flag_list(reference: int, values: List[bool]) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_coil_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to coil memory.

Parameters:

- **reference** – the reference to write to

- **value** – the int value to be written

```
write_coil_nibble_list(reference: int, values: List[int]) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_discrete_input(reference: int, value: int) → None
```

Read multiple discrete inputs from device memory

Parameters:

- **reference** – the register reference.
- **value** – the value to be written

Returns:
a list of discrete inputs where each element is `1` if the corresponding discrete input is set and `0` else.

```
write_discrete_input_bitfield(reference: int, value: int, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_discrete_input_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_discrete_input_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → None
```

Write data to discrete input device memory.

Parameters:

- **reference** – the discrete input reference.
- **data** – the type or instance or the decoder for the data

```
write_discrete_input_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_discrete_input_flag_list(reference: int, values: List[bool]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_discrete_input_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_discrete_input_nibble_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register(reference: int, value: int) → None
```

Write single holding register to device memory.

Parameters:

- **reference** – the register reference.
- **value** – the value to be written into the corresponding register.

```
write_holding_register_bdouble(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_bdouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_bfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_bfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_bitfield(reference: int, value: int, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_holding_register_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_holding_register_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → None
```

Write data to holding registers device memory.

Parameters:

- **reference** – the register reference.
- **data** – the type or instance or the decoder for the data

```
write_holding_register_double21436587(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 21436587-endian double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_double21436587_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 21436587-endian doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_double78563412(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 78563412-endian double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_double78563412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 78563412-endian doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_holding_register_flag_list(reference: int, values: List[bool]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_holding_register_float2143(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 2143-endian float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_float2143_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 2143-endian floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_float3412(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 3412-endian float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_float3412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 3412-endian floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_ldouble(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_ldouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_lfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_lfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_nibble_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 2143-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 21436587-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 21436587-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 2143-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 3412-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 3412-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 78563412-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 78563412-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_string(reference: int, value: bytes, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a string to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bytes value to be written
- **length** – the length of the value

```
write_holding_register_string_list(reference: int, values: List[bytes], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of strings to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bytes values to be written
- **length** – the length of the value

```
write_holding_register_ubint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 2143-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 21436587-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 21436587-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 2143-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 3412-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 3412-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 78563412-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 78563412-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register(reference: int, value: int) → None
```

Write single input register to device memory.

Parameters:

- **reference** – the register reference.
- **value** – the value to be written into the corresponding register.

```
write_input_register_bdouble(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_bdouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_bfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_bfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_bitfield(reference: int, value: int, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_input_register_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_input_register_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → None
```

Write data to input registers device memory.

Parameters:

- **reference** – the register reference.
- **data** – the type or instance or the decoder for the data

```
write_input_register_double21436587(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 21436587-endian double to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_double21436587_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 21436587-endian doubles to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_double78563412(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 78563412-endian double to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_double78563412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 78563412-endian doubles to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_input_register_flag_list(reference: int, values: List[bool]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_input_register_float2143(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 2143-endian float to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_float2143_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 2143-endian floats to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_float3412(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 3412-endian float to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_float3412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 3412-endian floats to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_ldouble(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_ldouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_lfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_lfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_nibble_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sbint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sbint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sbint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sbint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sbint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sbint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sbint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sbint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 2143-endian 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 21436587-endian 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 21436587-endian 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 2143-endian 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 3412-endian 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 3412-endian 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 78563412-endian 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 78563412-endian 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_slint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_slint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_slint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_slint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_slint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_slint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_slint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_slint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_string(reference: int, value: bytes, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a string to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bytes value to be written
- **length** – the length of the value

```
write_input_register_string_list(reference: int, values: List[bytes], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of strings to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bytes values to be written
- **length** – the length of the value

```
write_input_register_ubint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ubint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ubint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ubint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ubint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ubint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ubint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ubint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_uint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 2143-endian 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_uint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 21436587-endian 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_uint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 21436587-endian 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_uint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 2143-endian 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_uint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 3412-endian 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_uint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 3412-endian 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_uint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 78563412-endian 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_uint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 78563412-endian 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ulint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ulint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ulint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ulint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ulint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ulint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ulint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ulint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_multiple_coils(reference: int, values: List[int]) → None
```

Write multiple coils to device memory.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

```
write_multiple_discrete_inputs(reference: int, values: List[int]) → None
```

Write multiple discrete inputs to device memory.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

```
write_multiple_holding_registers(reference: int, values: List[int]) → None
```

Write multiple holding registers to device memory.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

```
write_multiple_input_registers(reference: int, values: List[int]) → None
```

Write multiple input registers to device memory.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

TLS Device

```
class htf.modbus.ModbusTLSDevice(bind_address: str, port: int = 502, shared_memory: bool =
False, certfile: str | None = None, keyfile: str | None = None, password: str | None = None,
request_parser: Type[SerialRTUModbusRequest] | Type[SerialASCIIModbusRequest] |
Type[TCPModbusRequest] = <class 'htf.modbus.protocol.TCPModbusRequest'>, response_parser:
Type[SerialRTUModbusResponse] | Type[SerialASCIIModbusResponse] | Type[TCPModbusResponse] =
<class 'htf.modbus.protocol.TCPModbusResponse'>, debuglevel: int | None = None)
```

Parameters:

- **bind_address** – the ip-address to listen on
- **port** – the port to listen on

- **shared_memory** – if set to `True` a single shared memory is used
- **callback** – the callback to handle requests
- **certfile** – path to TLS certificate
- **keyfile** – path to TLS keyfile
- **password** – TLS password
- **request_parser** – the request parser
- **response_parser** – the response parser
- **debuglevel** – the debuglevel (`None` disables debug, `1` prints requests and responses and `2` prints introspection)

```
close() → None
```

Close the device simulator and the server.

```
create_exception_response(request_pdu: RequestPDU, exception_code: str) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler to response with an exception.

Parameters:

- **request_pdu** – the request pdu
- **exception_code** – the exception code to be sent

Returns:
the response to be sent to the client

```
get_extended_memory(memory_number: int) → Dict[int, List[int]] | None
```

Get extended memory.

Parameters:
memory_number – the memory number (0x0001 to 0xFFFF)
Returns:
the extended memory at `memory_number` as a dict with key record numer and values list of
integers

Return type:
list of int
Raises:
KeyError – if the `memory_number` was not found in extended memory.

```
handle_function_code_1(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 1 ``` ``Read Coils`.``.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_15(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 15 `Write Multiple Coils`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_16(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 16 `Write Multiple Registers`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_2(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 2 `Read Discrete Inputs`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_20(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 20 `Read File Record`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_21(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 21 `Write File Record`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_22(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 22 `Mask Write Register`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_23(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 23 `Read/Write Multiple Registers`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_24(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 24 `Read FIFO Queue`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_3(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 3 `Read Holding Registers`.

Parameters:
pdu – the request pdu

Returns:
the response to be sent to the client

```
handle_function_code_4(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 4 `Read Input Registers`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_43(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Encapsulated Interface Transport.

Calls a handler by mei type with the name `handle_function_code_43_mei_type_<mei type>`. To add more mei types more handlers have to be added.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_43_mei_type_14(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Encapsulated Interface Transport: Read Device Identification. Basic object ids can be read.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_5(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 5 `Write Single Coil`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_function_code_6(pdu: RequestPDU) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for function code 6 `Write Single Register`.

Parameters:
pdu – the request pdu
Returns:
the response to be sent to the client

```
handle_request(adu: SerialRTUModbusRequest | SerialASCIIModbusRequest | TCPModbusRequest)
→ SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Request handler for an incoming request.

Parameters:
adu – a request adu
Returns:
the command or exception handler

```
mask_holding_register(reference: int, and_mask: int, or_mask: int) → None
```

Mask write single holding register from device memory.

Parameters:

- **reference** – the register reference
- **and_mask** – the and mask
- **or_mask** – the or mask

```
mask_multiple_holding_registers(reference: int, quantity: int, and_mask: int, or_mask:
int) → None
```

Mask write multiple holding registers from device memory.

Parameters:

- **reference** – the register reference
- **quantity** – the number of registers to be masked
- **and_mask** – the and mask
- **or_mask** – the or mask

```
read_coil(reference: int) → int
```

Read a single coil from device memory.

Parameters:

reference – the register reference.
Returns:
`1` if the coil is set and `0` else.

```
read_coil_bitfield(reference: int, length: int) → int
```

Read a bitfield from coil memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_coil_bitfield_list(reference: int, quantity: int, length: int) → List[int]
```

Read a list of bitfields from coil memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_coil_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct] |
Type[ByteType]) → ByteStruct | ByteType
```

Read data from coils device memory.

Parameters:

- **reference** – the coil reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_coil_flag(reference: int) → bool
```

Read a bit from coil memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_coil_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from coil memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_coil_nibble(reference: int) → int
```

Read a nibble from coil memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_coil_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from coil memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_discrete_input(reference: int) → int
```

Read single discrete input from device memory

Parameters:
reference – the register reference.
Returns:
`1` if the discrete input is set and `0` else.

```
read_discrete_input_bitfield(reference: int, length: int) → int
```

Read a bitfield from discrete input memory.

Parameters:

- **reference** – the reference to read from

- **length** – the length of the value

Returns:
int value read from `reference`

```
read_discrete_input_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_discrete_input_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct]
| Type[ByteType]) → ByteStruct | ByteType
```

Read data from discrete inputs device memory.

Parameters:

- **reference** – the discrete input reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_discrete_input_flag(reference: int) → bool
```

Read a bit from discrete input memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_discrete_input_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_discrete_input_nibble(reference: int) → int
```

Read a nibble from discrete input memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_discrete_input_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from discrete input memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register(reference: int) → int
```

Read a single holding register from device memory.

Parameters:
reference – the register reference.
Returns:
the holding register value

```
read_holding_register_bdouble(reference: int) → float
```

Read a double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_bdouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:

list of float values read from `reference`

```
read_holding_register_bfloat(reference: int) → float
```

Read a float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_bfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_bitfield(reference: int, length: int) → int
```

Read a bitfield from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_holding_register_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → ByteStruct | ByteType
```

Read data from holding registers device memory.

Parameters:

- **reference** – the register reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_holding_register_double21436587(reference: int) → float
```

Read a 21436587-endian double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_double21436587_list(reference: int, quantity: int) → List[float]
```

Read a list of 21436587-endian doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_double78563412(reference: int) → float
```

Read a 78563412-endian double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_double78563412_list(reference: int, quantity: int) → List[float]
```

Read a list of 78563412-endian doubles from holding register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_flag(reference: int) → bool
```

Read a bit from holding register memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_holding_register_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_holding_register_float2143(reference: int) → float
```

Read a 2143-endian float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_float2143_list(reference: int, quantity: int) → List[float]
```

Read a list of 2143-endian floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_float3412(reference: int) → float
```

Read a 3412-endian float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_float3412_list(reference: int, quantity: int) → List[float]
```

Read a list of 3412-endian floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_ldouble(reference: int) → float
```

Read a double from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_ldouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_lfloat(reference: int) → float
```

Read a float from holding register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_holding_register_lfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_holding_register_nibble(reference: int) → int
```

Read a nibble from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint16(reference: int) → int
```

Read a signed 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint32(reference: int) → int
```

Read a signed 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint64(reference: int) → int
```

Read a signed 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sbint8(reference: int) → int
```

Read a signed 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sbint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint2143(reference: int) → int
```

Read a signed 2143-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint21436587(reference: int) → int
```

Read a signed 21436587-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 21436587-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 2143-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint3412(reference: int) → int
```

Read a signed 3412-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 3412-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_sint78563412(reference: int) → int
```

Read a signed 78563412-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_sint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 78563412-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint16(reference: int) → int
```

Read a signed 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint32(reference: int) → int
```

Read a signed 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint64(reference: int) → int
```

Read a signed 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_slint8(reference: int) → int
```

Read a signed 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_slint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_string(reference: int, length: int) → bytes
```

Read a string from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
bytes value read from `reference`

```
read_holding_register_string_list(reference: int, quantity: int, length: int) → List[bytes]
```

Read a list of strings from holding register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of bytes values read from `reference`

```
read_holding_register_ubint16(reference: int) → int
```

Read an unsigned 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint32(reference: int) → int
```

Read an unsigned 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint64(reference: int) → int
```

Read an unsigned 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ubint8(reference: int) → int
```

Read an unsigned 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ubint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint2143(reference: int) → int
```

Read an unsigned 2143-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint21436587(reference: int) → int
```

Read an unsigned 21436587-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 21436587-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 2143-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint3412(reference: int) → int
```

Read an unsigned 3412-endian 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:

int value read from `reference`

```
read_holding_register_uint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 3412-endian 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_uint78563412(reference: int) → int
```

Read an unsigned 78563412-endian 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_uint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 78563412-endian 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint16(reference: int) → int
```

Read an unsigned 16-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint32(reference: int) → int
```

Read an unsigned 32-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint64(reference: int) → int
```

Read an unsigned 64-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_holding_register_ulint8(reference: int) → int
```

Read an unsigned 8-bit integer from holding register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_holding_register_ulint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from holding register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register(reference: int) → int
```

Read a single input register from device memory.

Parameters:
reference – the register reference.
Returns:
the input register value

```
read_input_register_bdouble(reference: int) → float
```

Read a double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_bdouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:

list of float values read from `reference`

```
read_input_register_bfloat(reference: int) → float
```

Read a float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_bfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_bitfield(reference: int, length: int) → int
```

Read a bitfield from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
int value read from `reference`

```
read_input_register_bitfield_list(reference: int, quantity: int, length: int) →
List[int]
```

Read a list of bitfields from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct]
| Type[ByteType]) → ByteStruct | ByteType
```

Read data from input registers from device memory.

Parameters:

- **reference** – the register reference
- **data** – the type or instance or the decoder for the data

Returns:
instance of `datatype` containing the read data

```
read_input_register_double21436587(reference: int) → float
```

Read a 21436587-endian double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_double21436587_list(reference: int, quantity: int) → List[float]
```

Read a list of 21436587-endian doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_double78563412(reference: int) → float
```

Read a 78563412-endian double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_double78563412_list(reference: int, quantity: int) → List[float]
```

Read a list of 78563412-endian doubles from input register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_flag(reference: int) → bool
```

Read a bit from input register memory.

Parameters:
reference – the reference to read from
Returns:
bool value read from `reference`

```
read_input_register_flag_list(reference: int, quantity: int) → List[bool]
```

Read a list of bits from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of bool values read from `reference`

```
read_input_register_float2143(reference: int) → float
```

Read a 2143-endian float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_float2143_list(reference: int, quantity: int) → List[float]
```

Read a list of 2143-endian floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_float3412(reference: int) → float
```

Read a 3412-endian float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_float3412_list(reference: int, quantity: int) → List[float]
```

Read a list of 3412-endian floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_ldouble(reference: int) → float
```

Read a double from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_ldouble_list(reference: int, quantity: int) → List[float]
```

Read a list of doubles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_lfloat(reference: int) → float
```

Read a float from input register memory.

Parameters:
reference – the reference to read from
Returns:
float value read from `reference`

```
read_input_register_lfloat_list(reference: int, quantity: int) → List[float]
```

Read a list of floats from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of float values read from `reference`

```
read_input_register_nibble(reference: int) → int
```

Read a nibble from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_nibble_list(reference: int, quantity: int) → List[int]
```

Read a list of nibbles from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint16(reference: int) → int
```

Read a signed 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint32(reference: int) → int
```

Read a signed 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint64(reference: int) → int
```

Read a signed 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sbint8(reference: int) → int
```

Read a signed 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sbint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint2143(reference: int) → int
```

Read a signed 2143-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint21436587(reference: int) → int
```

Read a signed 21436587-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 21436587-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 2143-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint3412(reference: int) → int
```

Read a signed 3412-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 3412-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_sint78563412(reference: int) → int
```

Read a signed 78563412-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_sint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 78563412-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from

- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint16(reference: int) → int
```

Read a signed 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint16_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint32(reference: int) → int
```

Read a signed 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint32_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint64(reference: int) → int
```

Read a signed 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint64_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_slint8(reference: int) → int
```

Read a signed 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_slint8_list(reference: int, quantity: int) → List[int]
```

Read a list of signed 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_string(reference: int, length: int) → bytes
```

Read a string from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value

Returns:
bytes value read from `reference`

```
read_input_register_string_list(reference: int, quantity: int, length: int) →
List[bytes]
```

Read a list of strings from input register memory.

Parameters:

- **reference** – the reference to read from
- **length** – the length of the value
- **quantity** – the number of elements to read

Returns:
list of bytes values read from `reference`

```
read_input_register_ubint16(reference: int) → int
```

Read an unsigned 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint32(reference: int) → int
```

Read an unsigned 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint64(reference: int) → int
```

Read an unsigned 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ubint8(reference: int) → int
```

Read an unsigned 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ubint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint2143(reference: int) → int
```

Read an unsigned 2143-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint21436587(reference: int) → int
```

Read an unsigned 21436587-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint21436587_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 21436587-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint2143_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 2143-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint3412(reference: int) → int
```

Read an unsigned 3412-endian 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:

int value read from `reference`

```
read_input_register_uint3412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 3412-endian 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_uint78563412(reference: int) → int
```

Read an unsigned 78563412-endian 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_uint78563412_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 78563412-endian 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint16(reference: int) → int
```

Read an unsigned 16-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint16_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 16-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint32(reference: int) → int
```

Read an unsigned 32-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint32_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 32-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint64(reference: int) → int
```

Read an unsigned 64-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint64_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 64-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_input_register_ulint8(reference: int) → int
```

Read an unsigned 8-bit integer from input register memory.

Parameters:
reference – the reference to read from
Returns:
int value read from `reference`

```
read_input_register_ulint8_list(reference: int, quantity: int) → List[int]
```

Read a list of unsigned 8-bit integers from input register memory.

Parameters:

- **reference** – the reference to read from
- **quantity** – the number of elements to read

Returns:
list of int values read from `reference`

```
read_multiple_coils(reference: int, quantity: int) → List[int]
```

Read multiple coils from device memory.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of coils to be read.

Returns:
a list of coil states where each element is `1` if the corresponding coil is set and `0` else.

```
read_multiple_discrete_inputs(reference: int, quantity: int) → List[int]
```

Read multiple discrete inputs from device memory.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of discrete inputs to be read.

Returns:
a list of discrete inputs where each element is `1` if the corresponding discrete input is set and `0` else.

```
read_multiple_holding_registers(reference: int, quantity: int) → List[int]
```

Read multiple holding registers from device memory.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of registers to be read.

Returns:
the holding register values

```
read_multiple_input_registers(reference: int, quantity: int) → List[int]
```

Read multiple input registers from device memory.

Parameters:

- **reference** – the register reference.
- **quantity** – the number of registers to be read.

Returns:
the input register values

```
set_device_identifier(object_id: int | None, value: str | bytes | None) → None
```

Set a device identifier. The objects `"vendor_name"`, `"product_code"`, `"major_minor_version"`, `"vendor_url"`, `"product_name"`, `"model_name"` and `"user_application_name"` are predefined.

Set `value` to `None` to remove an entry.

Entries can be read using Modbus function code 43.14.

Parameters:

- **object_id** – the object identifier
- **value** – the value to be used

```
set_extended_memory(memory_number: int, records: Dict[int, List[int]] | None) → None
```

Set extended memory that can be read with Modbus function code 20 and written with Modbus function code 21.

If `records` is `None` the memory is removed.

Parameters:

- **memory_number** – the memory number (0x0001 to 0xFFFF)
- **records** – the records to be stored as a dict with key record numer and values list of integers

```
set_fifo_queue_content(address: int, content: List[int] | None) → None
```

Set the FIFO queue content.

Parameters:

- **address** – the address
- **content** – a list of integers or `None` to delete the queue contents

```
write_coil(reference: int, value: int) → None
```

Write a single coil to device memory.

Parameters:

- **reference** – the register reference.
- **value** – the value to be written.

```
write_coil_bitfield(reference: int, value: int, length: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_coil_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_coil_data(reference: int, data: ByteStruct | ByteType | Type[ByteStruct] |
Type[ByteType]) → None
```

Write data to coils device memory.

Parameters:

- **reference** – the coil reference.
- **data** – the type or instance or the decoder for the data

```
write_coil_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_coil_flag_list(reference: int, values: List[bool]) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_coil_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to coil memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_coil_nibble_list(reference: int, values: List[int]) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to coil memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_discrete_input(reference: int, value: int) → None
```

Read multiple discrete inputs from device memory

Parameters:

- **reference** – the register reference.
- **value** – the value to be written

Returns:

a list of discrete inputs where each element is `1` if the corresponding discrete input is set and `0` else.

```
write_discrete_input_bitfield(reference: int, value: int, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_discrete_input_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_discrete_input_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → None
```

Write data to discrete input device memory.

Parameters:

- **reference** – the discrete input reference.
- **data** – the type or instance or the decoder for the data

```
write_discrete_input_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_discrete_input_flag_list(reference: int, values: List[bool]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_discrete_input_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_discrete_input_nibble_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to discrete input memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register(reference: int, value: int) → None
```

Write single holding register to device memory.

Parameters:

- **reference** – the register reference.
- **value** – the value to be written into the corresponding register.

```
write_holding_register_bdouble(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_bdouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_bfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_bfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_bitfield(reference: int, value: int, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_holding_register_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_holding_register_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → None
```

Write data to holding registers device memory.

Parameters:

- **reference** – the register reference.
- **data** – the type or instance or the decoder for the data

```
write_holding_register_double21436587(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 21436587-endian double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_double21436587_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 21436587-endian doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_double78563412(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 78563412-endian double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_double78563412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 78563412-endian doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_holding_register_flag_list(reference: int, values: List[bool]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_holding_register_float2143(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 2143-endian float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_float2143_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 2143-endian floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_float3412(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 3412-endian float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_float3412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 3412-endian floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_ldouble(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_ldouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_lfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_holding_register_lfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_holding_register_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_nibble_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sbint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sbint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 2143-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 21436587-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 21436587-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 2143-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 3412-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 3412-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_sint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 78563412-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_sint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 78563412-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_slint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_slint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_string(reference: int, value: bytes, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a string to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bytes value to be written
- **length** – the length of the value

```
write_holding_register_string_list(reference: int, values: List[bytes], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of strings to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bytes values to be written
- **length** – the length of the value

```
write_holding_register_ubint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ubint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ubint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 2143-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 21436587-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 21436587-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 2143-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 3412-endian 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 3412-endian 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_uint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 78563412-endian 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_uint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 78563412-endian 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_holding_register_ulint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to holding register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_holding_register_ulint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to holding register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register(reference: int, value: int) → None
```

Write single input register to device memory.

Parameters:

- **reference** – the register reference.
- **value** – the value to be written into the corresponding register.

```
write_input_register_bdouble(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_bdouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_bfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_bfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_bitfield(reference: int, value: int, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bitfield to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written
- **length** – the length of the value

```
write_input_register_bitfield_list(reference: int, values: List[int], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bitfields to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written
- **length** – the length of the value

```
write_input_register_data(reference: int, data: ByteStruct | ByteType |
Type[ByteStruct] | Type[ByteType]) → None
```

Write data to input registers device memory.

Parameters:

- **reference** – the register reference.
- **data** – the type or instance or the decoder for the data

```
write_input_register_double21436587(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 21436587-endian double to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_double21436587_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 21436587-endian doubles to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_double78563412(reference: int, value: float) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 78563412-endian double to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_double78563412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 78563412-endian doubles to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_flag(reference: int, value: bool) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a bit to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bool value to be written

```
write_input_register_flag_list(reference: int, values: List[bool]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of bits to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bool values to be written

```
write_input_register_float2143(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 2143-endian float to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_float2143_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 2143-endian floats to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_float3412(reference: int, value: float) → SerialRTUModbusResponse
| SerialASCIIModbusResponse | TCPModbusResponse
```

Write a 3412-endian float to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_float3412_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of 3412-endian floats to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_ldouble(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a double to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_ldouble_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of doubles to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_lfloat(reference: int, value: float) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a float to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the float value to be written

```
write_input_register_lfloat_list(reference: int, values: List[float]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of floats to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of float values to be written

```
write_input_register_nibble(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a nibble to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_nibble_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of nibbles to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sbint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sbint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sbint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sbint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sbint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sbint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sbint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sbint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 2143-endian 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 21436587-endian 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 21436587-endian 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 2143-endian 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 3412-endian 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 3412-endian 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_sint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 78563412-endian 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_sint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 78563412-endian 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_slint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 16-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_slint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 16-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_slint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_slint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_slint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_slint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_slint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write a signed 8-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_slint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of signed 8-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_string(reference: int, value: bytes, length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a string to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the bytes value to be written
- **length** – the length of the value

```
write_input_register_string_list(reference: int, values: List[bytes], length: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of strings to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of bytes values to be written
- **length** – the length of the value

```
write_input_register_ubint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ubint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ubint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ubint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ubint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ubint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ubint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ubint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_uint2143(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 2143-endian 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_uint21436587(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 21436587-endian 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_uint21436587_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 21436587-endian 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_uint2143_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 2143-endian 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_uint3412(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 3412-endian 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_uint3412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 3412-endian 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_uint78563412(reference: int, value: int) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 78563412-endian 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_uint78563412_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 78563412-endian 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ulint16(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 16-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ulint16_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 16-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ulint32(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 32-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ulint32_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 32-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ulint64(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 64-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ulint64_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 64-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_input_register_ulint8(reference: int, value: int) → SerialRTUModbusResponse |
SerialASCIIModbusResponse | TCPModbusResponse
```

Write an unsigned 8-bit integer to input register memory.

Parameters:

- **reference** – the reference to write to
- **value** – the int value to be written

```
write_input_register_ulint8_list(reference: int, values: List[int]) →
SerialRTUModbusResponse | SerialASCIIModbusResponse | TCPModbusResponse
```

Write a list of unsigned 8-bit integers to input register memory.

Parameters:

- **reference** – the reference to write to
- **values** – a list of int values to be written

```
write_multiple_coils(reference: int, values: List[int]) → None
```

Write multiple coils to device memory.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

```
write_multiple_discrete_inputs(reference: int, values: List[int]) → None
```

Write multiple discrete inputs to device memory.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

```
write_multiple_holding_registers(reference: int, values: List[int]) → None
```

Write multiple holding registers to device memory.

Parameters:

- **reference** – the register reference.

- **values** – the values to be written.

```
write_multiple_input_registers(reference: int, values: List[int]) → None
```

Write multiple input registers to device memory.

Parameters:

- **reference** – the register reference.
- **values** – the values to be written.

Create Device Simulators with Special Behaviour

You can add special behaviour to a device to use it in tests.

For example, to simulate a device that raises an `illegal_data_address` when addresses greater than `1000` are accessed, run the following code:

```
from htf.modbus import ModbusSerialRTUDevice
from htf.modbus.types import ModbusRequest, ModbusResponse, RequestPDU

class TestDevice(ModbusSerialRTUDevice):
    def handle_request(self, adu: ModbusRequest) -> ModbusResponse:
        if adu.pdu.data.starting_address.get() > 1000:
            return self.create_exception_response(adu.pdu, exception_code="illegal_data_address")
        else:
            return super(TestDevice, self).handle_request(adu)
```

The following example disables the function code `3` (read multiple holding registers) completely, returning an `illegal function` exception:

```
from htf.modbus import ModbusSerialRTUDevice
from htf.modbus.types import ModbusRequest, ModbusResponse, RequestPDU

class TestDevice(ModbusSerialRTUDevice):
    def handle_function_code_3(self, pdu: RequestPDU) -> ModbusResponse:
        return self.create_exception_response(pdu, exception_code="illegal_function")
```

Exceptions

```
class htf.modbus.ModbusException
```

A Modbus exception raised by clients.

```
add_note(object, /)
```

Exception.add_note(note) – add a note to the exception

```
args
```

```
with_traceback(object, /)
```

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

```
class htf.modbus.ModbusNoResponseException
```

A Modbus exception raised by clients if no response was received.

```
add_note(object, /)
```

Exception.add_note(note) – add a note to the exception

```
args
```

```
with_traceback(object, /)
```

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

```
class htf.modbus.ModbusChecksumException(value: str, object: Any)
```

A Modbus exception raised if the checksum is broken.

```
add_note(object, /)
```

Exception.add_note(note) – add a note to the exception

```
args
```

```
with_traceback(object, /)
```

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

Memory

Memory is used to realize devices' memory.

Memory Base

Memory base-class.

```
class htf.modbus.MemoryBase(memory: MemoryBase | bytearray | None = None)
```

MemoryBase is the Modbus memory base-class.

Parameters:
memory – the memory to address or `None` for new bytearray

Bit Array

```
class htf.modbus.BitArray(memory: MemoryBase | bytearray | None = None)
```

BitArray is a bit-aligned Modbus memory for coils and discrete inputs.

Parameters:
memory – the memory to address or `None` for new bytearray

Register Array

```
class htf.modbus.RegisterArray(memory: MemoryBase | bytearray | None = None)
```

RegisterArray is a 2 byte-aligned Modbus memory for input and holding registers.

Parameters:
memory – the memory to address or `None` for new bytearray

Modbus Memory

```
class htf.modbus.ModbusMemory(shared_memory: bool = False)
```

ModbusMemory represents the physical memory of a Modbus device. It supports reading and writing of: coils, discrete inputs, input and holding registers.

Parameters:
shared_memory – If set to `True` a single shared memory is used.

```
read_coil(reference: int) → int
```

Read a coil.

Parameters:
reference – reference index of the coil
Returns:
value of the coil

```
read_coils_as_int(reference: int, quantity: int) → int
```

Read one or more coils as an int.

Parameters:

- **reference** – reference index of the first coil
- **quantity** – number of bits to read

Returns:
value of coils as integer

```
read_discrete_input(reference: int) → int
```

Read a discrete input bit.

Parameters:
reference – reference index of the discrete input
Returns:
value of the discrete input bit

```
read_discrete_input_as_int(reference: int, quantity: int) → int
```

Read one or more discrete inputs as an int.

Parameters:

- **reference** – reference index of the first discrete input
- **quantity** – number of bits to read

Returns:
value of discrete inputs as integer

```
read_holding_register(reference: int) → bytearray
```

Read a holding register.

Parameters:
reference – reference index of the holding register
Returns:
value of the holding register

```
read_input_register(reference: int) → bytearray
```

Read a input register.

Parameters:
reference – reference index of the input register
Returns:
value of the input register

```
write_coil(reference: int, value: int) → None
```

Write one coil.

Parameters:

- **reference** – reference index of the coil
- **value** – value to set the coil to

```
write_discrete_input(reference: int, value: int) → None
```

Write one discrete input.

Parameters:

- **reference** – reference index of the discrete input
- **value** – value to set the discrete input to

```
write_holding_register(reference: int, value: bytearray) → None
```

Write a holding register.

Parameters:

- **reference** – reference index of the holding register
- **value** – value to set the holding register to

```
write_input_register(reference: int, value: bytearray) → None
```

Write a input register.

Parameters:

- **reference** – reference index of the input register
- **value** – value to set the input register to

```
write_multiple_coils(reference: int, quantity: int, values: List[int]) → None
```

Write one or multiple coils.

Parameters:

- **reference** – reference index of the first coil
- **values** – values to set the coils to

```
write_multiple_discrete_inputs(reference: int, quantity: int, values: List[int]) → None
```

Write one or multiple discrete inputs.

Parameters:

- **reference** – reference index of the first discrete input
- **values** – values to set the discrete input to

```
write_multiple_holding_registers(reference: int, values: List[bytearray]) → None
```

Write one or multiple holding registers.

Parameters:

- **reference** – reference index of the first holding register
- **values** – values to set the holding register to

```
write_multiple_input_registers(reference: int, values: List[bytearray]) → None
```

Write one or multiple input registers.

Parameters:

- **reference** – reference index of the first input register
- **values** – values to set the input register to

Protocol

Requests and Responses

Requests and responses are used as Modbus communication messages for different transports.

Serial RTU Request

Serial RTU request.

```
class htf.modbus.SerialRTUModbusRequest
```

Modbus Serial RTU request.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Serial RTU Response

Serial RTU response.

```
class htf.modbus.SerialRTUModbusResponse
```

Modbus Serial RTU response.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.

Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Serial ASCII Request

Serial ASCII request.

```
class htf.modbus.SerialASCIIModbusRequest
```

Modbus Serial ASCII request.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Serial ASCII Response

Serial ASCII response.

```
class htf.modbus.SerialASCIIModbusResponse
```

Modbus Serial ASCII response.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.

- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

TCP Request

The TCP request object which is also used for TLS.

```
class htf.modbus.TCPModbusRequest
```

Modbus TCP request.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.

- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

TCP Response

The TCP response object which is also used for TLS.

```
class htf.modbus.TCPModbusResponse
```

Modbus TCP response.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.

- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Function Code

```
class htf.modbus.FunctionCode(value: int = 0, format: str | None = None)
```

Parameters:

- **value** – the initial value.
- **format=None** – Use “hex” to format values to hexadecimal. Use “bin” to format values to binary.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.

- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
get() → int
```

Return the value.

Returns:
the value.

```
get_byte_size() → int
```

Return the length of the byte type in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the length of the byte type in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
is_exception() → bool
```

Check if the current function code is an exception (msb is set).

Returns:
`True` if the current function code is an exception. Else `False`.

```
root() → ByteStruct | BitStruct
```

return root element

```
set(value: int) → None
```

Set the value.

Parameters:
value – the new value

```
set_fuzzing_values(values: Generator[Any, None, None] | List[Any] | None) → None
```

Set fuzzing values.

Parameters:
values – the values used for fuzzing.

```
up() → ByteStruct | BitStruct
```

Return the parent element.

PDU

```
class htf.modbus.ModbusPDUBase
```

ModbusPDUBase is the Modbus PDU base-class.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Request PDU

```
class htf.modbus.RequestPDU
```

RequestPDU is the request protocol data unit class.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.

- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
requests_generator() → Generator[Tuple[int, ByteStruct | BitStruct | ByteType |
BitType], None, None]
```

Yields function code, abstraction tuples.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Response PDU

```
class htf.modbus.ResponsePDU
```

ResponsePDU is the response protocol data unit class.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.

- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
responses_generator() → Generator[Tuple[int, ByteStruct | BitStruct | ByteType |
BitType], None, None]
```

Yields function code, abstraction tuples.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Exception Response

`htf.modbus.ExceptionResponse` is a base class for all Modbus responses. In case of an exception the payload is truncated automatically. Thus no special handling is needed.

```
class htf.modbus.ExceptionResponse
```

ExceptionResponse is the response class representing invalid requests or device failures. It's the base-class of all responses.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Read Coils Request

```
class htf.modbus.ReadCoilsRequest
```

Representation of a read coils request.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Read Coils Response

```
class htf.modbus.ReadCoilsResponse
```

Representation of a read coils response.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.

- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Read Discrete Inputs Request

```
class htf.modbus.ReadDiscreteInputsRequest
```

Representation of a read discrete inputs request.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.

Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.

Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Read Discrete Inputs Response

```
class htf.modbus.ReadDiscreteInputsResponse
```

Representation of a read discrete inputs response.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Read Holding Registers Request

```
class htf.modbus.ReadHoldingRegistersRequest
```

Representation of a read holding registers request.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Read Holding Registers Response

```
class htf.modbus.ReadHoldingRegistersResponse
```

Representation of a read holding registers response.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Read Input Registers Request

```
class htf.modbus.ReadInputRegistersRequest
```

Representation of a read input registers request.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Read Input Registers Response

```
class htf.modbus.ReadInputRegistersResponse
```

Representation of a read input registers response.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Write Single Coils Request

```
class htf.modbus.WriteSingleCoilRequest
```

Representation of a write single coil request.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Write Single Coils Response

```
class htf.modbus.WriteSingleCoilResponse
```

Representation of a write single coil response.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Write Single Register Request

```
class htf.modbus.WriteSingleRegisterRequest
```

Representation of a write single register request.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Write Single Register Response

```
class htf.modbus.WriteSingleRegisterResponse
```

Representation of a write single register response.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Read Exception Status Request

```
class htf.modbus.ReadExceptionStatusRequest
```

Representation of a read exception status request.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Read Exception Status Response

```
class htf.modbus.ReadExceptionStatusResponse
```

Representation of a read exception status response.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Variable Length Data

```
class htf.modbus.VariableLengthData(length: Callable | int | None = None, value: bytes |
str = b'', padding: bytes | str = b'\x00')
```

VariableLengthData is a class that holds an arbitrary amount of data. Its length depends on the protocol it's embedded in.

Parameters:

- **length=None** – states the string length. Can be a callable (e.g. lambda) or a scalar. If set to `None` the result is a null-terminated string. If set to an Integer the result is a fixed length string padded with `padding`. If set to a `callable` (lambda or function) the result is a fixed or variable length string padded with `padding`.
- **value=""** – the initial string value.
- **padding="x00"** – that padding pattern used for filling the encoded data if *value* is shorter than *length*.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
get() → bytes
```

Return the value.

```
get_byte_size() → int
```

Return the size in bytes.

```
get_size() → int
```

Return the size in bytes.

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
set(value: bytes | str) → None
```

Set the value.

Parameters:
value – the new value

```
set_fuzzing_values(values: Generator[Any, None, None] | List[Any] | None) → None
```

Set fuzzing values.

Parameters:
values – the values used for fuzzing.

```
set_length(length: Callable | int | None) → None
```

Set the length.

Parameters:
length=None – states the string length. Can be a callable (e.g. lambda) or a scalar. If set to `None` the result is a null-terminated string. If set to an Integer the result is a fixed length string padded with `padding`. If set to a `callable` (lambda or function) the result is a fixed or variable length string padded with `padding`.

```
up() → ByteStruct | BitStruct
```

Return the parent element.

Diagnostics Request

```
class htf.modbus.DiagnosticsRequest
```

Representation of a diagnostics request.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Diagnostics Response

```
class htf.modbus.DiagnosticsResponse
```

Representation of a diagnostics response.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Get Communication Event Counter Request

```
class htf.modbus.GetCommEventCounterRequest
```

Representation of a get communication event counter request.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Get Communication Event Counter Response

```
class htf.modbus.GetCommEventCounterResponse
```

Representation of a get communication event counter response.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Get Communication Event Log Request

```
class htf.modbus.GetCommEventLogRequest
```

Representation of a get communication event log request.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Get Communication Event Log Response

```
class htf.modbus.GetCommEventLogResponse
```

Representation of a get communication event log response.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Write Multiple Coils Request

```
class htf.modbus.WriteMultipleCoilsRequest
```

Representation of a write multiple coils request.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Write Multiple Coils Response

```
class htf.modbus.WriteMultipleCoilsResponse
```

Representation of a write multiple coils response.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Write Multiple Registers Request

```
class htf.modbus.WriteMultipleRegistersRequest
```

Representation of a write multiple registers request.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Write Multiple Registers Response

```
class htf.modbus.WriteMultipleRegistersResponse
```

Representation of a write multiple registers response.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Report Server ID Request

```
class htf.modbus.ReportServerIdRequest
```

Representation of a report server id request.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Report Server ID Response

```
class htf.modbus.ReportServerIdResponse
```

Representation of a report server id response.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Read Extended Memory Record Sub Request

```
class htf.modbus.ReadExtendedMemoryRecordSubRequest
```

Representation of a read extended memory record sub request.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Read Extended Memory Record Request

```
class htf.modbus.ReadExtendedMemoryRecordRequest
```

Representation of a read extended memory record request.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Read Extended Memory Record Response

```
class htf.modbus.ReadExtendedMemoryRecordResponse
```

Representation of a read extended memory record response.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Write Extended Memory Record Sub Request

```
class htf.modbus.WriteExtendedMemoryRecordSubRequest
```

Representation of a write extended memory record sub request.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Write Extended Memory Record Request

```
class htf.modbus.WriteExtendedMemoryRecordRequest
```

Representation of a write extended memory record request.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Write Extended Memory Record Response

```
class htf.modbus.WriteExtendedMemoryRecordResponse
```

Representation of a write extended memory record response.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Mask Write Request

```
class htf.modbus.MaskWriteRequest
```

Representation of a mask write request.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Mask Write Response

```
class htf.modbus.MaskWriteResponse
```

Representation of a mask write response.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Read Write Multiple Registers Request

```
class htf.modbus.ReadWriteMultipleRegistersRequest
```

Representation of a write multiple registers request.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Read Write Multiple Registers Response

```
class htf.modbus.ReadWriteMultipleRegistersResponse
```

Representation of a write multiple registers response.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Read FIFO Queue Request

```
class htf.modbus.ReadFifoQueueRequest
```

Representation of a read fifo queue request.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Read FIFO Queue Response

```
class htf.modbus.ReadFifoQueueResponse
```

Representation of a read fifo queue response.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Encapsulated Interface Transport Request

```
class htf.modbus.EncapsulatedInterfaceTransportRequest
```

Representation of an encapsulated interface transport request.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Encapsulated Interface Transport Response

```
class htf.modbus.EncapsulatedInterfaceTransportResponse
```

Representation of an encapsulated interface transport response.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Device Identification Object

```
class htf.modbus.ReadDeviceIdentificationObject
```

Representation of read device identification object.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

CRC

```
class htf.modbus.ModbusCrc
```

Calculates a reversed IBM-CRC-16 (0x8005) -> 0xa001 to be used with Modbus

```
crc(data: bytes) → int
```

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
get() → int
```

Return the value.

Returns:
the value.

```
get_byte_size() → int
```

Return the length of the byte type in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the length of the byte type in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
set(value: int) → None
```

Set the value.

Parameters:
value – the new value

```
set_fuzzing_values(values: Generator[Any, None, None] | List[Any] | None) → None
```

Set fuzzing values.

Parameters:
values – the values used for fuzzing.

```
up() → ByteStruct | BitStruct
```

Return the parent element.

LRC

```
class htf.modbus.ModbusLRC
```

Compute the logitudinal redudancy check for Modbus.

Parameters:

- **value** – the initial value.
- **format=None** – Use “hex” to format values to hexadecimal. Use “bin” to format values to binary.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
get() → int
```

Return the value.

Returns:
the value.

```
get_byte_size() → int
```

Return the length of the byte type in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the length of the byte type in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
lrc(data: bytes) → int
```

```
root() → ByteStruct | BitStruct
```

return root element

```
set(value: int) → None
```

Set the value.

Parameters:

value – the new value

```
set_fuzzing_values(values: Generator[Any, None, None] | List[Any] | None) → None
```

Set fuzzing values.

Parameters:
values – the values used for fuzzing.

```
up() → ByteStruct | BitStruct
```

Return the parent element.

Changelog

htf-modbus-3.2.0

- ship `cp312-abi3` wheels that are compatible with Python 3.12 and newer versions

htf-modbus-3.1.11

- implement Cyber Resilience Act Conformity (CRA)
- update dependencies

htf-modbus-3.1.10

- fix extended memory implementation in `htf.modbus.ModbusTCPDevice` and `htf.modbus.ModbusUDPDevice`

htf-modbus-3.1.9

- add serial parameters to device simulators
- add methods to break checksums in clients, servers and devices for testing purposes
- fix bit order for function code 15
- fix LRC calculation

htf-modbus-3.1.8

- add support for Python 3.13

htf-modbus-3.1.7

- fix handling of address `0xFFFF` in `htf.modbus.ModbusTCPDevice` and `htf.modbus.ModbusUDPDevice`

htf-modbus-3.1.6

- add requirements for validation purposes

htf-modbus-3.1.5

- add build environment data for validation purposes

htf-modbus-3.1.4

- `htf-modbus` can now be used standalone

htf-modbus-3.1.3

- add support for Python 3.12

htf-modbus-3.1.2

- improve connection handling in `htf.modbus.ModbusTCPDevice` and `htf.modbus.ModbusUDPDevice`

htf-modbus-3.1.1

- fix not correctly closed TCP connections in `htf.modbus.ModbusTCPDevice`
- add timeout to `htf.modbus.ModbusTCPDevice`

htf-modbus-3.1.0

- add type-hints
- use `hlm-3.1`
- use `oser-3.1`

htf-modbus-3.0.2

- add support for oser-3.1

htf-modbus-3.0.1

- add support for Python 3.11

htf-modbus-3.0.0

- extract `htf-modbus` from `htf`

HART — The HART Testing Framework

The HART Testing Framework enables users to

- write automatable tests for HART slaves
- simulate HART devices and HART masters
- add device specific commands
- develop and debug a HART device interactively using the HART-Shell
- monitor HART messages using the HART-Monitor

- send corrupted frames and
- run HART Fuzzing tests

It is based on version 7.6 of the HART specification and implements all universal and common practice commands (0..533). Extended commands up to 16-bit are supported.

You need the `hart` feature in your license to unlock the HART Testing Framework.

HART Interface

The `HartInterface` implements the data link layer and physical layer. It enables you to write binary data that is sent to the connected HART devices and read HART frames.

The used serial port must support the `RS485 mode` that sets `RTS` high while sending. Many USB-Uarts do not support this feature and thus cannot be used.

It is recommended to use USB-HART-Modems such as the MACTek Viator. They do support this feature and are known to work.

Real COM ports are very sparse nowadays.

```
class htf.hart.HartInterface(comport: str, timeout: int | float = 0.3)
```

Data-Link-Layer and Physical-Layer for HART.

Parameters:

- **comport** – the comport to be used where the HART modem is connected to. Must support RS485 mode.
- **timeout=.3** – the time out for a single byte. Timeouts in `read()` are multiple of this timeout.

```
close() → None
```

Close the HART interface. Is called in __del__, too.

```
get_last_preamble_count() → int
```

Gets the count of preambles that was most recently received. This does **NOT** require a full HART frame to be read, but does require the preambles to be followed by a valid delimiter.

Returns:
the most recently received number of consecutive preambles
Return type:
int

```
query(data: bytes, number_of_preambles: int = 5, preamble: bytes = b'\xff', timeout: int
| float = 1.0) → bytes | None
```

Query a HART command.

Parameters:

- **request** – the hart frame to be sent.
- **number_of_preambles=5** – the number of preambles.
- **preamble='\xff'** – `number_of_preambles` times `preamble` is sent before the frame content is sent.
- **timeout=1.0** – the timeout in seconds.

Returns:
if no frame was received `None` is returned else a HART frame is returned.
Return type:
bytes or None

```
read(timeout: int | float = 1.0) → bytes | None
```

Read a frame.

Parameters:
timeout=1.0 – the timeout in seconds.
Returns:
if no frame was received `None` is returned else a HART frame is returned.
Return type:
bytes or None

```
write(data: bytes, number_of_preambles: int = 5, preamble: bytes = b'\xff') → None
```

Write a HART frame.

Parameters:

- **data** – the bytes to be sent.
- **number_of_preambles=5** – the number of preambles.
- **preamble='\xff'** – `number_of_preambles` times `preamble` is sent before the frame content is sent.

Example:

```
import oser
from htf.hart import HartInterface

hi = HartInterface(comport="/dev/ttyUSB1")
cmd0_request = b"\x02\x80\x00\x00\x82"
response = hi.query(cmd0_request)
print(oser.to_hex(response))
   0|  1|  2|  3|  4|  5|  6|  7|  8|  9| 10| 11| 12| 13| 14| 15| 16| 17| 18
\x06\x80\x00\x0e\x00\x00\x00\x13\x37\x00\x00\x00\x00\x00\x00\x00\x00\x23\x8f
hi.close()
```

HART Frame

The `HartFrame` abstracts the HART-PDU that is used for HART communication.

It is based on OSER and lets the user specify device specific commands.

The check byte is generated automatically when `encode` is called.

```
class htf.hart.HartFrame(command: int | None = None, auto_length: bool = True,
auto_checkbyte: bool = True)
```

A HART frame abstraction.

Parameters:

- **command=None** – the HART command number.
- **auto_length=True** – if set to `True` the byte count of the HART frame is calculated automatically when calling `encode`.
- **auto_checkbyte=True** – if set to `True` the checkbyte of the HART frame is calculated automatically when calling `encode`.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string. `byte_count` is set automatically if `auto_length` is supplied.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_command_request_parser(command: int) → ByteStruct
```

Get a command request parser.

Parameters:
command – the command number to be returned.
Returns:
the command parser.
Return type:
ByteStruct
Raises:

- **KeyError** – Raises a `KeyError` if the command if the command
- **is not set.** –

```
get_command_response_parser(command: int) → ByteStruct
```

Get a command response parser.

Parameters:
command – the command number to be returned.
Returns:

the command parser.
Return type:
ByteStruct
Raises:

- **KeyError** – Raises a `KeyError` if the command if the command
- **is not set.** –

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
requests_generator() → Generator[Tuple[int, ByteStruct | BitStruct | ByteType |
BitType], None, None]
```

A generator that yields command, parser tuples for requests.

This method shall be overwritten to realize device specific commands.

Yields:
tuples of command and parser

```
responses_generator() → Generator[Tuple[int, ByteStruct | BitStruct | ByteType |
BitType], None, None]
```

A generator that yields command, parser tuples for responses.

This method shall be overwritten to realize device specific commands.

Yields:
tuples of command and parser

```
root() → ByteStruct | BitStruct
```

return root element

```
set_auto_check_byte_enable(enable_auto_check_byte: bool = True) → None
```

Enable or disable the automatic checkbyte calculation on `encode`.

Parameters:
enable_auto_check_byte=True – the new enable state.

```
set_auto_length_enable(enable_auto_length: bool = True) → None
```

Enable or disable the auto length feature.

Parameters:
enable_auto_length=True – the new enable state.

```
set_command_request_parser(command: int, parser: ByteStruct | BitStruct | ByteType |
BitType) → None
```

Set a command request parser. This overwrites exising command parsers.

Parameters:

- **command** – the command number to be set.
- **parser** – the parser for the command.

```
set_command_response_parser(command: int, parser: ByteStruct | BitStruct | ByteType |
BitType) → None
```

Set a command response parser. This overwrites exising command parsers.

Parameters:

- **command** – the command number to be set.
- **parser** – the parser for the command.

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Example:

```
import oser
from htf.hart import HartFrame

hf = HartFrame(1)
hf.address.address.set(0x13370023)
encoded = hf.encode()
print(hf)
HartFrame():
    delimiter: Delimiter():
        address_type: 'unique' (Flag)
        number_of_expansion_bytes: 0 (BitField(2))
        physical_layer_type: 'asynchronous' (BitField(2))
        frame_type: 'stx' (BitField(3))
    address: Address():
        master_address: 'primary_master' (Flag)
        burst_mode: 0 (Flag)
        address: 322371619 (BitField(38))
    expansion_bytes: Array():
    [
    ]
    command: 1 (UBInt8)
    byte_count: 0 (UBInt8)
    payload: Command1_ReadPrimaryVariableRequest():
    check_byte: 4 (CheckByte)

print(oser.to_hex(encoded))
   0|  1|  2|  3|  4|  5|  6|  7|  8
\x82\x80\x13\x37\x00\x23\x01\x00\x04
```

HART Application Layer

The HART Application Layer interfaces the `HartInterface` and the abstracted protocol with `HartFrame`.

It lets the user communicate with a single HART device easily.

Additionally you can search for HART devices, set the master address and the device address.

```
class htf.hart.HartApplicationLayer(interface: HartInterface, decoder_generator:
Type[HartFrame] | Callable[[...], HartFrame] | None = None)
```

HART Application-Layer.

Parameters:

- **interface** – the HART interface to be used.
- **decoder_generator=None** – a callable that returns a HartFrame instance with or without device specific commands.

```
close() → None
```

Close the HART application layer and close the HART interface supplied. Is called in __del__, too.

```
find_device(polling_addresses: List[int] | None = None) → int
```

Find the first HART device by polling all addresses stated in `polling_addresses` and use the first device found.

If no device is found an `AssertionError` is raised.

Parameters:
polling_addresses=[0] – the polling addresses used to find a HART device.
Returns:
Unique HART address of the first device found in polling.
Return type:
int

```
poll_devices(polling_addresses: List[int] | None = None) → Generator[int, None, None]
```

Poll `polling_addresses` to find HART devices.

Parameters:
polling_addresses=[0] – list of HART polling addresses
Yields:
int – HART device addresses

```
query(request: HartFrame, number_of_preambles: int = 5, preamble: bytes = b'\xff',
timeout: int | float = 1.0) → HartFrame | None
```

Query a HART command. The HART frame is encoded automatically.

Parameters:

- **request** – the hart frame to be sent.
- **number_of_preambles=5** – the number of preambles.
- **preamble='ÿ'** – `number_of_preambles` times `preamble` is sent before the frame content is sent.
- **timeout=1.0** – the timeout in seconds.

Returns:
if no frame was received `None` is returned.
Return type:
HartFrame or None

```
read(timeout: int | float = 1.0) → HartFrame | None
```

Read a message using the interface and decode it using the decoder.

Parameters:

timeout=1.0 – the timeout in seconds.
Returns:
if no frame was received `None` is returned.
Return type:
HartFrame or None

```
set_decoder_generator(decoder_generator: Type[HartFrame] | Callable[[...], HartFrame] |
None = None) → None
```

Set the frame generator.

Parameters:
decoder_generator=HartFrame – when called returns

```
set_device_address(device_address: int) → None
```

Set the current HART device address.

Parameters:
device_address – the HART device address to be used (<= 38 bits)

```
set_master_address(master_address: str) → None
```

Set the current simulated master address.

Parameters:
master_address – “primary_master” or “secondary_master”

```
write(frame: HartFrame, number_of_preambles: int = 5, preamble: bytes = b'\xff') → None
```

Write a HART frame. The HART frame is encoded automatically.

Except for command 0 the HART device address is set automatically before sending the frame content.

Parameters:

- **frame** – the hart frame to be sent.
- **number_of_preambles=5** – the number of preambles.
- **preamble='ÿ'** – `number_of_preambles` times `preamble` is sent before the frame content is sent.

Find device at polling address 0 manually:

```
import oser
from htf.hart import \
     HartInterface, HartApplicationLayer, HartFrame

hi = HartInterface(comport="/dev/ttyUSB1")
```

```
hal = HartApplicationLayer(hi)

# search for HART device at polling address 0 manually
cmd0_request = HartFrame(0)
cmd0_request.delimiter.frame_type.set("stx")
cmd0_request.delimiter.address_type.set("polling")
cmd0_request.address.address.set(0)
print(cmd0_request)
HartFrame():
    delimiter: Delimiter():
        address_type: 'polling' (Flag)
        number_of_expansion_bytes: 0 (BitField(2))
        physical_layer_type: 'asynchronous' (BitField(2))
        frame_type: 'stx' (BitField(3))
    address: Address():
        master_address: 'primary_master' (Flag)
        burst_mode: 0 (Flag)
        address: 0 (BitField(6))
    expansion_bytes: Array():
    [
    ]
    command: 0 (UBInt8)
    byte_count: 0 (UBInt8)
    payload: Command0_ReadUniqueIdentifierRequest():
    check_byte: 0 (CheckByte)

response = hal.query(cmd0_request)
print(response)
HartFrame():
    delimiter: Delimiter():
        address_type: 'polling' (Flag)
        number_of_expansion_bytes: 0 (BitField(2))
        physical_layer_type: 'asynchronous' (BitField(2))
        frame_type: 'ack' (BitField(3))
    address: Address():
        master_address: 'primary_master' (Flag)
        burst_mode: 0 (Flag)
        address: 0 (BitField(6))
    expansion_bytes: Array():
    [
    ]
    command: 0 (UBInt8)
    byte_count: 14 (UBInt8)
    payload: Command0_ReadUniqueIdentifierResponse():
        response_code: 'success' (UBInt8)
        field_device_status:  (FieldDeviceStatus)
        data_object_id: 0 (UBInt8)
        device_type: 4919 (UBInt16)
        minimum_preambles_request: 0 (UBInt8)
        protocol_revision: 0 (UBInt8)
        device_revision_level: 0 (UBInt8)
        software_revision_level: 0 (UBInt8)
        hardware_revision_level_and_physical_signaling_code: 0 (UBInt8)
        flags: 0 (UBInt8)
        device_id: BitStruct():
            value: 35 (BitField(24))
    check_byte: 143 (CheckByte)

device_address = (response.payload.device_type.get() << 24) +\
     response.payload.device_id.value.get()
```

```
print("0x%x" % device_address)
0x1337000023
hal.close()
```

Find device at polling address 0:

```
import oser
from htf.hart import \
     HartInterface, HartApplicationLayer

hi = HartInterface(comport="/dev/ttyUSB1")
hal = HartApplicationLayer(hi)

# search for HART device at polling address 0
device_address = hal.find_device()
print("0x%x" % device_address)
0x1337000023
hal.close()
```

Poll addresses 0 .. 9:

```
import oser
from htf.hart import \
     HartInterface, HartApplicationLayer

hi = HartInterface(comport="/dev/ttyUSB1")
hal = HartApplicationLayer(hi)

# poll address 0 .. 9
device_addresses = hal.poll_devices(range(10))
for device_address in device_addresses:
    print("0x%x" % device_address)

0x1337000023

hal.close()
```

Query Command 1 from first found HART device and print primary variable:

```
import oser
from htf.hart import \
     HartInterface, HartApplicationLayer, HartFrame

hi = HartInterface(comport="/dev/ttyUSB1")
hal = HartApplicationLayer(hi)

# search for HART device at polling address 0
hal.find_device()
82527125539

# query command 1
cmd1_request = HartFrame(1)
```

```
response = hal.query(cmd1_request)

print(response)
HartFrame():
    delimiter: Delimiter():
        address_type: 'unique' (Flag)
        number_of_expansion_bytes: 0 (BitField(2))
        physical_layer_type: 'asynchronous' (BitField(2))
        frame_type: 'ack' (BitField(3))
    address: Address():
        master_address: 'primary_master' (Flag)
        burst_mode: 0 (Flag)
        address: 82527125539 (BitField(38))
    expansion_bytes: Array():
    [
    ]
    command: 1 (UBInt8)
    byte_count: 7 (UBInt8)
    payload: Command1_ReadPrimaryVariableResponse():
        response_code: 'buffer_overflow' (UBInt8)
        field_device_status: non-primary_variable_out_of_limits (FieldDeviceStatus)
        units: 123 (UBInt8)
        primary_variable: 456.78900146484375 (BFloat)
    check_byte: 193 (CheckByte)

primary_variable = response.payload.primary_variable.get()
print("PV:", primary_variable)
PV: 456.78900146484375
hal.close()
```

Data Types

The data types implement the needed components to build HART frames.

Packed ASCII

`PackedASCII` implements the `Packed ASCII` data type for the HART protocol.

```
class htf.hart.data_types.PackedASCII(length: Callable | int | None = None, value: bytes |
str = b'', padding: bytes | str = b'\x00')
```

The HART Packed ASCII data type

Parameters:

- **length=None** – states the string length. Can be a callable (e.g. lambda) or a scalar. If set to an Integer the result is a fixed length string padded with `padding`. If set to a `callable` (lambda or function) the result is a fixed or variable length string padded with `padding`. The length must be a multiple of three.
- **value=""** – the initial string value.
- **padding="\x00"** – that padding pattern used for filling the encoded data if *value* is shorter than *length*.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the encoded binary string.
Return type:
bytes

```
get() → bytes
```

Return the value.

```
get_byte_size() → int
```

Return the size in bytes.

```
get_size() → int
```

Return the size in bytes.

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
set(value: bytes | str) → None
```

Set the value.

Parameters:
value – the new value

```
set_fuzzing_values(values: Generator[Any, None, None] | List[Any] | None) → None
```

Set fuzzing values.

Parameters:
values – the values used for fuzzing.

```
set_length(length: Callable | int | None) → None
```

Set the length.

Parameters:
length=None – states the string length. Can be a callable (e.g. lambda) or a scalar. If set to `None` the result is a null-terminated string. If set to an Integer the result is a fixed length string padded with `padding`. If set to a `callable` (lambda or function) the result is a fixed or variable length string padded with `padding`.

```
up() → ByteStruct | BitStruct
```

Return the parent element.

Example:

```
import oser
from htf.hart import PackedASCII

pa = PackedASCII(length=6, value=b"ABCDEFGH")
encoded = pa.encode()
print(oser.to_hex(encoded))
   0|  1|  2|  3|  4|  5
\x04\x20\xc4\x14\x61\xc8
pa2 = PackedASCII(length=3, value=b"ABC")
```

```
pa2.decode(encoded)
3
print(pa2)
b'ABCD'
```

Date

`Date` implements the `Date` data type for the HART protocol.

```
class htf.hart.data_types.Date(date: date)
```

The HART Date data type

Parameters:
date – an instance of `datetime.date` or `datetime.datetime` between `1900-01-01` and `2155-12-31`.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the encoded binary string.
Return type:
bytes

```
get() → date
```

Return the value.

```
get_byte_size() → int
```

Return the size in bytes.

```
get_size() → int
```

Return the size in bytes.

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
set(value: date) → None
```

Set the value.

Parameters:
value – the new value

```
set_fuzzing_values(values: Generator[Any, None, None] | List[Any] | None) → None
```

Set fuzzing values.

Parameters:
values – the values used for fuzzing.

```
set_length(length: Callable | int | None) → None
```

Set the length.

Parameters:

length=None – states the string length. Can be a callable (e.g. lambda) or a scalar. If set to `None` the result is a null-terminated string. If set to an Integer the result is a fixed length string padded with `padding`. If set to a `callable` (lambda or function) the result is a fixed or variable length string padded with `padding`.

```
up() → ByteStruct | BitStruct
```

Return the parent element.

Example:

```
import oser
from htf.hart import Date
import datetime

date = Date(datetime.date(2017, 1, 11))
encoded = date.encode()
print(oser.to_hex(encoded))
   0|  1|  2
\x75\x01\x0b
date2 = Date(None)
date2.decode(encoded)
3
print(date2)
datetime.date(2017, 1, 11)
```

Time

`Time` implements the `Time` data type for the HART protocol.

```
class htf.hart.data_types.Time(time: time)
```

The HART Time data type.

Parameters:
time – an instance of `datetime.time` or `datetime.datetime` between `00:00:00` and `23:59:59`.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.

Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
get() → time
```

Return the value.

Returns:
the value.

```
get_byte_size() → int
```

Return the length of the byte type in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the length of the byte type in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
set(value)
```

Set the value.

Parameters:
value – the new value

```
set_fuzzing_values(values: Generator[Any, None, None] | List[Any] | None) → None
```

Set fuzzing values.

Parameters:
values – the values used for fuzzing.

```
up() → ByteStruct | BitStruct
```

Return the parent element.

Example:

```
import oser
from htf.hart import Time

import datetime

time = Time(datetime.time(23, 24, 7, 1000))
encoded = time.encode()
print(oser.to_hex(encoded))
   0|  1|  2|  3
\xa0\xb0\x3b\x20
time2 = Time(None)
time2.decode(encoded)
4
print(time2)
23:24:07.001000 (Time)
```

Response Code

`ResponseCode` implements the `Response Code` data type for the HART protocol.

When printed the states are concatenated with `;`.

```
class htf.hart.data_types.ResponseCode(**kwargs: int)
```

HART device specific response code generator.

`0: "success"` is added automatically.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** (*bytes*) – the data buffer that is decoded.
- **full_data** (*bytes*) – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** (*bytes*) – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** (*bytes*) – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** (*bytes*) – the binary data of the current context. The user normally does not need to supply this.

Returns:
the encoded binary string.
Return type:
bytes

```
get() → str
```

Return the value.

Returns:
the value

```
get_byte_size() → int
```

Return the size in bytes.

```
get_size() → int
```

Return the size in bits or bytes, depending on the prototype.

```
get_value() → Any
```

Return the raw value.

Returns:
the raw value.
Return type:
object

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None (*object*) – stop introspection at `stop_at`.

```
is_error() → bool
```

Checks if the response code is of class ‘error’ or not. Warning response codes must have the ‘warning_’-prefix. If there is no prefix the response is considered to be an error.

```
root() → ByteStruct | BitStruct
```

return root element

```
set(value: Any) → None
```

Set the value.

Parameters:
value – the new value

```
set_fuzzing_values(values: Generator[Any, None, None] | List[Any] | None) → None
```

Set fuzzing values.

Parameters:

values (*iterable*) – the values used for fuzzing.

```
up() → ByteStruct | BitStruct
```

Return the parent element.

If the MSB of the response code's value is set a communication error is represented:

```
import oser
from htf.hart import ResponseCode

response_code = ResponseCode()
response_code.set(0x82)
encoded = response_code.encode()
print(oser.to_hex(encoded))
   0
\x82
print(response_code)
'buffer_overflow' (UBInt8)

response_code2 = ResponseCode()
response_code2.decode(b"\xff")
1
print(response_code2)
'vertical_perity_error; overrun_error; framing_error; longitudinal_error; buffer_overflow' (UBInt8)
```

If the MSB is not set a command specific response code can be represented. Command specific response codes are passed to `ResponseCode` as named parameters.

```
import oser
from htf.hart import ResponseCode

class Command48_ReadAdditionalDeviceStatusResponse(oser.ByteStruct):
     """
     HART command 48 response abstraction.
     """
     def __init__(self):
         super(Command48_ReadAdditionalDeviceStatusResponse, self).__init__()

         self.response_code = ResponseCode(
                 error_device_specific_command_error=6,
                 warning_update_in_progress=8,
                 error_access_restricted=16,
                 error_busy=32)
         self.data = oser.String(length=3)
         # ...

c48 = Command48_ReadAdditionalDeviceStatusResponse()
c48.response_code.set(32)
print(c48)
Command48_ReadAdditionalDeviceStatusResponse():
```

```
    response_code: 'error_busy' (UBInt8)
    data: b''

encoded = c48.encode()
print(oser.to_hex(encoded))
   0|  1|  2|  3
\x20\x00\x00\x00

c48_2 = Command48_ReadAdditionalDeviceStatusResponse()
c48_2.decode(b"\x08\x00\x00\x00")
4
print(c48_2)
Command48_ReadAdditionalDeviceStatusResponse():
    response_code: 'warning_update_in_progress' (UBInt8)
    data: b'\x00\x00\x00'
```

Field Device Status

`FieldDeviceStatus` implements the `Field Device Status` data type for the HART protocol.

When printed the states are concatenated with `;`.

```
class htf.hart.data_types.FieldDeviceStatus(value: int = 0, format: str | None = None)
```

HART Field Device Status data type.

Parameters:

- **value** – the initial value.
- **format=None** – Use “hex” to format values to hexadecimal. Use “bin” to format values to binary.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
get() → int
```

Return the value.

Returns:
the value.

```
get_byte_size() → int
```

Return the length of the byte type in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the length of the byte type in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
set(value: int) → None
```

Set the value.

Parameters:
value – the new value

```
set_fuzzing_values(values: Generator[Any, None, None] | List[Any] | None) → None
```

Set fuzzing values.

Parameters:
values – the values used for fuzzing.

```
up() → ByteStruct | BitStruct
```

Return the parent element.

The `FieldDeviceStatus` is a bit field for predefined values:

```
import oser
from htf.hart import FieldDeviceStatus

fds = FieldDeviceStatus(0x42)
print(fds)
configuration_changed; non-primary_variable_out_of_limits (FieldDeviceStatus)

fds2 = FieldDeviceStatus(0x02)
print(fds2)
non-primary_variable_out_of_limits (FieldDeviceStatus)

encoded = fds2.encode()
print(oser.to_hex(encoded))
   0
\x02

fds3 = FieldDeviceStatus(0x00)
fds3.decode(encoded)
1
print(fds3)
non-primary_variable_out_of_limits (FieldDeviceStatus)
```

HART Responses

`HartResponse` implements a `HART response` data type to automatically handle error responses. All HART responses should be derived from this class.

```
class htf.hart.data_types.HartResponse
```

A ByteStruct for HART responses which checks for error response codes in _items() and stops iteration after field_device_status. All HART responses should be derived from this class.

```
decode(data: bytes, full_data: bytes = b'', context_data: bytes = b'') → int
```

Decode a binary string and return the number of bytes that were decoded.

Parameters:

- **data** – the data buffer that is decoded.
- **full_data** – the binary data string until the part to be decoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

Returns:
the number of bytes that were decoded.
Return type:
int

```
encode(full_data: bytes = b'', context_data: bytes = b'') → bytes
```

Return the encoded binary string.

Parameters:

- **full_data** – the binary data string until the part to be encoded. The user normally does not need to supply this.
- **context_data** – the binary data of the current context. The user normally does not need to supply this.

```
from_dict(data: Dict) → None
```

Fill self with data.

Parameters:
data – data to be used to fill the calling instance.

```
fuzzing_iterator(copy: bool = False) → Generator[Any, None, None]
```

The fuzzing iterator iterates over all combinations of set fuzzing values (`oser.ByteType.set_fuzzing_values`). If no fuzzing values are set the current struct is yielded.

Parameters:
copy=False – if set to `True` the generated fuzzing values are deep copies of the original. Creating these deep copies is slow. If set to `False` the original struct is retruned and the generated value must be used immediately since the next generated overwrites the values on the same value.
Yields:
the fuzzing combinations.

```
get_byte_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
get_size() → int
```

Return the size in bytes.

Returns:
the length of the byte type in bytes.
Return type:
int

```
introspect(stop_at: ByteStruct | BitStruct | ByteType | BitType | None = None) → str
```

Return the introspection representation of the object as a string.

Parameters:
stop_at=None – stop introspection at `stop_at`.

```
root() → ByteStruct | BitStruct
```

return root element

```
to_dict() → Dict
```

Return self as a dict()

```
up() → ByteStruct | BitStruct
```

return parent element

Universal Commands

Command 0

Command 0 example:

```
import oser
from htf.hart import HartFrame
# request
hf = HartFrame(0)
print(hf)
    HartFrame():
```

```
        delimiter: Delimiter():
            address_type: 'polling' (Flag)
            number_of_expansion_bytes: 0 (BitField(2))
            physical_layer_type: 'asynchronous' (BitField(2))
            frame_type: 'stx' (BitField(3))
        address: Address():
            master_address: 'primary_master' (Flag)
            burst_mode: False (Flag)
            address: 0x0 (PollingAddress(6))
        expansion_bytes: Array():
        [
        ]
        command: 0 (Command)
        byte_count: 0 (UBInt8)
        payload: Command0_ReadUniqueIdentifierRequest():
        check_byte: 130 (CheckByte)

encoded = hf.encode()
print(oser.to_hex(encoded))
   0|  1|  2|  3|  4
\x02\x80\x00\x00\x82
# response
hf = HartFrame(0)
hf.delimiter.frame_type.set("ack")
print(hf)
HartFrame():
    delimiter: Delimiter():
        address_type: 'polling' (Flag)
        number_of_expansion_bytes: 0 (BitField(2))
        physical_layer_type: 'asynchronous' (BitField(2))
        frame_type: 'ack' (BitField(3))
    address: Address():
        master_address: 'primary_master' (Flag)
        burst_mode: False (Flag)
        address: 0x0 (PollingAddress(6))
    expansion_bytes: Array():
    [
    ]
    command: 0 (Command)
    byte_count: 14 (UBInt8)
    payload: Command0_ReadUniqueIdentifierResponse():
        response_code: 'success' (UBInt8)
        field_device_status:  (FieldDeviceStatus)
        data_object_id: 0 (UBInt8)
        device_type: 0 (UBInt16)
        minimum_preambles_request: 0 (UBInt8)
        protocol_revision: 0 (UBInt8)
        device_revision_level: 0 (UBInt8)
        software_revision_level: 0 (UBInt8)
        hardware_revision_level_and_physical_signaling_code: 0 (UBInt8)
        flags: 0 (UBInt8)
        device_id: BitStruct():
            value: 0 (BitField(24))
    check_byte: 136 (CheckByte)

encoded = hf.encode()
print(oser.to_hex(encoded))
   0|  1|  2|  3|  4|  5|  6|  7|  8|  9| 10| 11| 12| 13| 14| 15| 16| 17| 18
\x06\x80\x00\x0e\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x88
```

Command 1

Command 1 example:

```
import oser
from htf.hart import HartFrame
# request
hf = HartFrame(1)
print(hf)
    HartFrame():
        delimiter: Delimiter():
            address_type: 'unique' (Flag)
            number_of_expansion_bytes: 0 (BitField(2))

```

Device Specific Commands

To realize device specific commands `HartFrame` must be subclassed and the methods `requests_generator` and `responses_generator` must be overwritten.

Both methods are generators that yield tuples consisting of the command number and a device specific parser.

It is recommended to use `oser.Lazy` to wrap the parser to speed up the initialization of the HART frame.

In the following example the command 48 and 181 are implemented:

```
from oser import \
    ByteStruct, BitStruct, BitField, Switch, String, \
    Enum, UBInt8, Lazy, BFloat, to_hex
from htf.hart import HartFrame, ResponseCode, FieldDeviceStatus

class Command48_ReadAdditionalDeviceStatusRequest(ByteStruct):
    def __init__(self):
        super(Command48_ReadAdditionalDeviceStatusRequest, self).__init__()
        self.device_specific_status = BitStruct()
        self.device_specific_status.value = BitField(length=48)
        self.extended_device_status = UBInt8()
        self.device_operating_mode = UBInt8()
        self.status0 = UBInt8()
```

```
        self.status1 = UBInt8()
        self.analog_channel_saturated = UBInt8()
        self.status2 = UBInt8()
        self.status3 = UBInt8()
        self.analog_channel_fixed = UBInt8()
        self.device_specific_status = BitStruct()
        self.device_specific_status.value = BitField(length=88)

class Command48_ReadAdditionalDeviceStatusResponse(ByteStruct):
    def __init__(self):
        super(Command48_ReadAdditionalDeviceStatusResponse, self).__init__()

        self.response_code = ResponseCode(
                error_device_specific_command_error=6,
                warning_update_in_progress=8,
                error_access_restricted=16,
                error_busy=32)
        self.field_device_status = FieldDeviceStatus()

        self.device_specific_status = BitStruct()
        self.device_specific_status.value = BitField(length=48)
        self.extended_device_status = UBInt8()
        self.device_operating_mode = UBInt8()
        self.status0 = UBInt8()
        self.status1 = UBInt8()
        self.analog_channel_saturated = UBInt8()
        self.status2 = UBInt8()
        self.status3 = UBInt8()
        self.analog_channel_fixed = UBInt8()
        self.device_specific_status = BitStruct()
        self.device_specific_status.value = BitField(length=88)

class Command181_SetAnalogOutputRequest(ByteStruct):
    def __init__(self):
        super(Command181_SetAnalogOutputRequest, self).__init__()
        self.temporary_analog_output = Enum(
            prototype=UBInt8,
            values={
                    "invalid": 0x07,
                    "beamblock_signal": 0x06,
                    "fixed_current": 0x05,
                    "current_corresponding_to_gas_concentration": 0x04,
                    "maintenance_signal": 0x03,
                    "error_signal": 0x02,
                    "warning_signal": 0x01,
                    "analog_normal": 0x00,
                    },
            value="invalid",
            strict=True)
        self.gas_concentration = BFloat(.0)
        self.fixed_current_mA = BFloat(.0)

class Command181_SetAnalogOutputResponse(ByteStruct):
    def __init__(self):
        super(Command181_SetAnalogOutputResponse, self).__init__()

        self.response_code = ResponseCode()
```

```
        self.field_device_status = FieldDeviceStatus()

        self.temporary_analog_output = Enum(
            prototype=UBInt8,
            values={
                    "invalid": 0x07,
                    "beamblock_signal": 0x06,
                    "fixed_current": 0x05,
                    "current_corresponding_to_gas_concentration": 0x04,
                    "maintenance_signal": 0x03,
                    "error_signal": 0x02,
                    "warning_signal": 0x01,
                    "analog_normal": 0x00,
                    },
            value="invalid",
            strict=True)
        self.gas_concentration = BFloat(.0)
        self.fixed_current_mA = BFloat(.0)

class DeviceHartFrame(HartFrame):

    def requests_generator(self):
        # this is only needed in subclass hierarchies
        for command, parser in super(DeviceHartFrame, self).requests_generator():
            yield command, parser
        # the following commands are device specific
        yield 48, Lazy(Command48_ReadAdditionalDeviceStatusRequest)
        yield 181, Lazy(Command181_SetAnalogOutputRequest)

    def responses_generator(self):
        # this is only needed in subclass hierarchies
        for command, parser in super(DeviceHartFrame, self).responses_generator():
            yield command, parser
        # the following commands are device specific
        yield 48, Lazy(Command48_ReadAdditionalDeviceStatusResponse)
        yield 181, Lazy(Command181_SetAnalogOutputResponse)
```

These commands can be easily adapted for the customer's needs.

In the following example the usage is demonstrated.

```
# command 48
hf = DeviceHartFrame(command=48)

# request
hf.delimiter.frame_type.set("stx")

binary = hf.encode()
print(hf)
    DeviceHartFrame():
        delimiter: Delimiter():
            address_type: 'unique' (Flag)
            number_of_expansion_bytes: 0 (BitField(2))
            physical_layer_type: 'asynchronous' (BitField(2))
            frame_type: 'stx' (BitField(3))
        address: Address():
```

```
            master_address: 'primary_master' (Flag)
            burst_mode: 0 (Flag)
            address: 0 (BitField(38))
        expansion_bytes: Array():
        [
        ]
        command: 48 (UBInt8)
        byte_count: 19 (UBInt8)
        payload: Command48_ReadAdditionalDeviceStatusRequest():
            device_specific_status: BitStruct():
                value: 0 (BitField(88))

```

Protocol Factory

A protocol factory creates device specific HART frame abstractions respecting the device type or device address.

It is useful for the HART-shell and the HART-monitor.

A protocol factory needs two methods that return a device specific HART frame by device type or device address (in which the device type is included).

```
from htf.hart import HartFrame
from htf.hart.universal_commands import \
    Command48_ReadAdditionalDeviceStatusRequest,\
    Command48_ReadAdditionalDeviceStatusResponse
from oser import Lazy
import logging
logger = logging.getLogger(__name__)
logging.basicConfig(level=logging.DEBUG)

class DeviceHartFrame(HartFrame):
    def requests_generator(self):
        # here come the device specific commands
        yield 48, Lazy(Command48_ReadAdditionalDeviceStatusRequest)

    def responses_generator(self):
        # here come the device specific commands
        yield 48, Lazy(Command48_ReadAdditionalDeviceStatusResponse)

_frame_parser_db = {
    # the two LSBs in the device type cannot be used in the
    # device address so they must be masked
    0x1337 & 0x3fff: ["SpecificHartDevice", DeviceHartFrame],
    # ...
}
```

```
def get_hart_frame_by_device_type(device_type):
    """
    Create a HartFrame with device specific commands
    for the given device type.

    Args:
        device_type (int): the device type to be used

    Returns:
        HartFrame: a HartFrame generator for device specific commands
    """
    logger.info("Selecting frame by device type 0x%010x" % device_type)
    # the two LSBs in the device type cannot be used in the
    # device address so they must be masked
    device_type = device_type & 0x3fff
    try:
        name, DeviceSpecificHartFrame = _frame_parser_db[device_type]
        logger.info(
            "Found specific frame parser for %s (0x%x)" %
            (name, device_type))

        def _generator(command=None, auto_length=True):
            return DeviceSpecificHartFrame(command=command, auto_length=auto_length)

        return _generator
    except KeyError:
        logger.info("No specific frame parser found for device id 0x%010x. "
                    "Using default HartFrame()." % device_type)
        return HartFrame

def get_hart_frame_by_device_address(device_address):
    """
    Create a HartFrame with device specific commands
    for the given device address by extracting the
    device type from the device address

    Args:
        device_address (int): the device address to be used

    Returns:
        HartFrame: a HartFrame generator for device specific commands
    """
    device_type = device_address >> 24
    return get_hart_frame_by_device_type(device_type)
```

An exemplary usage looks like:

```
DeviceSpecificHartFrame = get_hart_frame_by_device_type(device_type=0x1337)
hf = DeviceSpecificHartFrame(command=48)
print(hf)
    DeviceHartFrame():
        delimiter: Delimiter():
            address_type: 'unique' (Flag)
            number_of_expansion_bytes: 0 (BitField(2))
            physical_layer_type: 'asynchronous' (BitField(2))
```

```
            frame_type: 'stx' (BitField(3))
        address: Address():
            master_address: 'primary_master' (Flag)
            burst_mode: 0 (Flag)
            address: 0 (BitField(38))
        expansion_bytes: Array():
        [
        ]
        command: 48 (UBInt8)
        byte_count: 0 (UBInt8)
        payload: Command48_ReadAdditionalDeviceStatusRequest():
            device_specific_status: BitStruct():
                value: 0 (BitField(88))
            extended_device_status: 0 (UBInt8)
            device_operating_mode: 0 (UBInt8)
            status0: 0 (UBInt8)
            status1: 0 (UBInt8)
            analog_channel_saturated: 0 (UBInt8)
            status2: 0 (UBInt8)

```

HART-Shell

The HART-shell enables you to develop and debug a HART device interactively. It is intended to be used interactively but can also be used non-interactively. The HART-shell is also customizable.

```
class htf.hart.HartShell(comport: str | None = None, decoder_generator: Type[HartFrame] |
Callable[[...], HartFrame] | None = None, protocol_factory: Callable[[...], Type[HartFrame]]
| None = None, timeout: int | float | None = None, interactive: bool = True, loglevel: int |
None = 2, argv: List[str] | None = None)
```

A HART Shell that can be used interactively.

Parameters:

- **comport** – the comport to be used where the HART modem is connected to.
- **decoder_generator=None** – a callable that returns a HartFrame instance with or without device specific commands.
- **protocol_factory=None** – a protocol factory that returns a device specific HART frame parser with respect to the supplied device type.
- **timeout=None** – the default timeout in seconds.
- **interactive=True** – if set to `True` the HART Shell becomes interactive.
- **loglevel=2** – set loglevel for loggnig to `loglevel`.
- **argv=None** – used for testing, etc.

```
close() → None
```

Close the HART application layer and close the HART interface supplied. Is called in __del__, too.

```
cmd(command: int, inputs: List[Any] | None = None, edit_all: bool = False, interactive:
bool = True, timeout: int | float | None = None) → HartFrame | None
```

Query a HART command.

Parameters:

- **command** – the HART command number.
- **inputs=None** – the inputs to be set in order to be put into the HART request.
- **edit_all=False** – if set to `True` and the HART shell runs interactively all request fields are edited interactively.
- **interactive=True** – if set to `True` the request is edited interactively.
- **timeout=None** – the timeout in seconds. If `None` is supplied the default timeout is used. If the default timeout is not set 1.0 is used.

```
find_device(polling_addresses: List[int] | None = None) → int | None
```

Find the first HART device by polling all addresses stated in `polling_addresses` and use the first device found.

If no device is found an `AssertionError` is raised.

Parameters:
polling_addresses=[0] – the polling addresses used to find a HART device.
Returns:
Unique HART address of the first device found in polling.
Return type:
int

```
last_preamble_count() → int
```

Returns the number of preambles most recently received by the HartInterface.

Returns:
number of preambles
Return type:
int

```
last_response() → HartFrame | Any | None
```

Get the last response.

The last received packet can also be access via `self.response`.

Returns:
the last received packet.
Return type:
object

```
list_device_commands(commands: List[int] | None = None) → List[int]
```

List the implemented commands of a HART device. Helps to find undocumented commands.

Parameters:
commands – the list of commands to be probed. If set to `None` `0 .. 255` is used.
Returns:
the implemented commands.
Return type:
list of int

```
poll_devices(polling_addresses: List[int] | None = None) → None
```

Poll `polling_addresses` to find HART devices.

Parameters:
polling_addresses=[0] – list of HART polling addresses

```
set_decoder_by_device_address(device_address: int) → None
```

Select the frame decoder and encoder by the device address

Parameters:
device_address – the device address

```
set_decoder_generator(decoder_generator: Type[HartFrame] | Callable[[...], HartFrame] |
None = None) → None
```

Set the frame generator.

Parameters:
decoder_generator=HartFrame – a parser for HART frames.

```
set_device_address(device_address: int) → None
```

Set the current HART device address.

Parameters:
device_address – the HART device address to be used (<= 38 bits)

```
set_loglevel(loglevel: int | None) → None
```

Set the loglevel.

Loglevel `0` means `quiet`.

Loglevel `1` means `binary` output. All packets are printed in a compact binary format.

Loglevel `2` means `binary+payload of interest` output. All packets are printed in a compact binary format. Additionally the interesting payload is printed. `response_code` is left out if it is `success` and `field_device_status` is left out in case of `0`. Other payload is printed line by line.

Loglevel `3` means `binary+whole packet` output. All packets are printed in a compact binary format. Additionally the packets are fully printed.

Parameters:
loglevel – Set loglevel to `loglevel`.

```
set_master_address(master_address: int) → None
```

Set the current simulated master address.

Parameters:
master_address – “primary_master” or “secondary_master”

```
set_number_of_preambles(number_of_preambles: int) → None
```

Set the number of preambles for requests.

Parameters:
number_of_preambles – the number of preambles for requests.

```
set_protocol_factory(protocol_factory: Callable[[...], Type[HartFrame]] | None = None) →
None
```

Set the protocol factory.

Parameters:
protocol_factory=None – a protocol factory that returns a device specific HART frame parser with respect to the supplied device type.

```
set_timeout(timeout: int | float | None) → None
```

Set the default timeout.

Parameters:
timeout – the default timeout in seconds

Interactive usage

`htf` comes with a HART-shell command line utility called `hart-shell`.

When run interactively all methods in `htf.hart.HartShell` are put into the local namespace so they can be run by entering the name.

Additionally macros are created for each possible command, eg. `cmd0`, `cmd1`, `..`, `cmd255`. These can be run by name, too.

The command line utility is based on IPython. IPython allows tab-completion. To enter long commands enter the first characters and press `TAB` and select the command using the arrow keys.

To run the `hart-shell` simply enter

```
$ hart-shell -c <comport>
```

Show help

```
$ hart-shell -h
usage: hart-shell [-h] -c COMPORT [-d Protocol database] [-t timeout]
                  [-v loglevel] [-V]

hart-shell - HILSTER Testing Framework (HILSTER GmbH, http://hilster.io)

optional arguments:
  -h, --help            show this help message and exit
  -c COMPORT, --comport COMPORT
                        comport for HART communication
  -d Protocol database, --database Protocol database
                        An import string to the protocol database where device
                        specific HART frames can be found. See docs for
                        details.
  -t timeout, --timeout timeout
                        The default timeout for commands.
  -v loglevel, --loglevel loglevel
                        The loglevel: 0: quiet, 1: binary, 2: binary+payload
                        of interest, 3: binary+debug
  -V, --version         Show version and exit
```

Find and select the first device

To find and select a device `htf.hart.HartShell.find_device` is used. If a device or multiple devices are found the first device address is selected and the address is used for all other commands entered.

Find and select the first device for polling address `0`:

```
In [1]: find_device()
Using first device with address 0x1337000023
```

Find and select the first device for polling addresses `0..9`:

```
In [2]: find_device(range(10))
Using first device with address 0x1337000023
```

Poll devices

To poll HART devices `htf.hart.HartShell.poll_devices` is used.

To poll polling address `0` enter:

```
In [1]: poll_devices()
Found 1 HART device.
0x1337000023
```

To poll polling addresses `0..9` enter:

```
In [2]: poll_devices(range(10))
Found 1 HART device.
0x1337000023
```

Set the timeout

The timeout for commands can be set using `htf.hart.HartShell.set_timeout`.

To set the timeout to `3.0` seconds enter:

```
In [1]: set_timeout(3.0)
```

Device selection

To select a device manually the device address can be set using `htf.hart.HartShell.set_device_address`.

To set the device address to `0x1337000024` enter:

```
In [1]: set_device_address(0x1337000024)
```

Running commands interactively

You can run commands interactively to debug, test and develop a HART-device. The easiest way is to enter `cmd` plus the command number to be run, eg. `cmd1` to run command 1.

By default the device address selected by `htf.hart.HartShell.find_device` or set by `htf.hart.HartShell.set_device_address` is used automatically.

To select a device and run command 1 on it enter:

```
In [1]: find_device()
Using first device with address 0x1337000023
Out[1]: 82527125539

In [2]: cmd1()
Running Command 1
Request:
HartFrame():
    delimiter: Delimiter():
        address_type: 'unique' (Flag)
        number_of_expansion_bytes: 0 (BitField(2))
        physical_layer_type: 'asynchronous' (BitField(2))
        frame_type: 'stx' (BitField(3))
    address: Address():
        master_address: 'primary_master' (Flag)
        burst_mode: 0 (Flag)
        address: 0 (BitField(38))
    expansion_bytes: Array():
    [
    ]
    command: 1 (UBInt8)
    byte_count: 0 (UBInt8)
    payload: Command1_ReadPrimaryVariableRequest():
    check_byte: 0 (CheckByte)

Response:
HartFrame():
    delimiter: Delimiter():
        address_type: 'unique' (Flag)
        number_of_expansion_bytes: 0 (BitField(2))
        physical_layer_type: 'asynchronous' (BitField(2))
        frame_type: 'ack' (BitField(3))
    address: Address():
        master_address: 'primary_master' (Flag)
        burst_mode: 0 (Flag)
        address: 82527125539 (BitField(38))
    expansion_bytes: Array():
    [
    ]
    command: 1 (UBInt8)
    byte_count: 7 (UBInt8)
    payload: Command1_ReadPrimaryVariableResponse():
        response_code: 'buffer_overflow' (UBInt8)
        field_device_status: non-primary_variable_out_of_limits (FieldDeviceStatus)
        units: 123 (UBInt8)
        primary_variable: 456.78900146484375 (BFloat)
    check_byte: 193 (CheckByte)

Out[2]: <htf.hart.protocol.HartFrame at 0x7fb4d4165080>
```

The timeout set by `htf.hart.HartShell.set_timeout` is used if not specified for the specific comamnd. To set the timeout add a `timeout=3.0` agrument.

```
In [3]: cmd1(timeout=3.0)
```

Loglevel

The loglevel can be set via commandline using the `-v` option or within the HART-Shell using

```
In [1]: set_loglevel(loglevel)
```

The values for `loglevel` reach from `0` to `3`. `0` means quiet. `1` means binary short form. `2` means binary short form and payload of interest. `3` means binary short form and debug.

The following example lists all loglevel usages:

```
In [1]: find_device()
Using first device with address 0x52eb021ce5
Out[1]: 356130102501

In [2]: set_loglevel(0)

In [3]: cmd1()
Out[3]: <htf.hart.protocol.HartFrame at 0x7419a90>

In [4]: set_loglevel(1)

In [5]: cmd1()
STX: 5FF 82 92EB021CE5 01
ACK: 5FF 86 92EB021CE5 00508B7FE00000 06
Out[5]: <htf.hart.protocol.HartFrame at 0x71da278>

In [6]: set_loglevel(2)

In [7]: cmd1()
STX: 5FF 82 92EB021CE5 01
ACK: 5FF 86 92EB021CE5 00508B7FE00000 06
field_device_status: 80
units: 139
primary_variable: nan
Out[7]: <htf.hart.protocol.HartFrame at 0x1f862e8>

In [8]: set_loglevel(3)

In [9]: cmd1()
STX: 5FF 82 92EB021CE5 01
HartFrame():
    delimiter: Delimiter():
        address_type: 'unique' (Flag)
        number_of_expansion_bytes: 0 (BitField(2))
        physical_layer_type: 'asynchronous' (BitField(2))
        frame_type: 'stx' (BitField(3))
    address: Address():
        master_address: 'primary_master' (Flag)
        burst_mode: 0 (Flag)
        address: 0x52eb021ce5 (SlaveAddress(38))
    expansion_bytes: Array():
    [
    ]
    command: 1 (Command)
```

```
    byte_count: 0 (UBInt8)
    payload: Command1_ReadPrimaryVariableRequest():
    check_byte: 1 (CheckByte)

ACK: 5FF 86 92EB021CE5 00508B7FE00000 06
HartFrame():
    delimiter: Delimiter():
        address_type: 'unique' (Flag)
        number_of_expansion_bytes: 0 (BitField(2))
        physical_layer_type: 'asynchronous' (BitField(2))
        frame_type: 'ack' (BitField(3))
    address: Address():
        master_address: 'primary_master' (Flag)
        burst_mode: 0 (Flag)
        address: 0x12eb021ce5 (SlaveAddress(38))
    expansion_bytes: Array():
    [
    ]
    command: 1 (Command)
    byte_count: 7 (UBInt8)
    payload: Command1_ReadPrimaryVariableResponse():
        response_code: 'success' (UBInt8)
        field_device_status: configuration_changed; more_status_available (FieldDeviceStatus)
        units: 139 (UBInt8)
        primary_variable: nan (BFloat)
    check_byte: 6 (CheckByte)

Out[9]: <htf.hart.protocol.HartFrame at 0x6ed22b0>
```

The default loglevel is `2`.

Set the number of preambles

You can set the number of preambles for requests using

```
In [1]: set_number_of_preambles(3)

In [2]: cmd1()
STX: 3FF 82 92EB021CE5 01
ACK: 5FF 86 92EB021CE5 00508B7FE00000 06
field_device_status: 80
units: 139
primary_variable: 0.0
Out[2]: <htf.hart.protocol.HartFrame at 0x7238ef0>

In [3]: set_number_of_preambles(5)

In [4]: cmd1()
STX: 5FF 82 92EB021CE5 01
ACK: 5FF 86 92EB021CE5 00508B7FE00000 06
field_device_status: 80
units: 139
primary_variable: nan
Out[4]: <htf.hart.protocol.HartFrame at 0x6edab70>
```

Access last response

The last response can be accessed using `self.response`.

```
In [1]: find_device()
Using first device with address 0x52eb021ce5
Out[1]: 356130102501

In [2]: cmd1()
STX: 5FF 82 92EB021CE5 01
ACK: 5FF 86 92EB021CE5 00508B7FE00000 06
field_device_status: 80
units: 139
primary_variable: nan
Out[2]: <htf.hart.protocol.HartFrame at 0x7014240>

In [3]: print(self.response)
HartFrame():
    delimiter: Delimiter():
        address_type: 'unique' (Flag)
        number_of_expansion_bytes: 0 (BitField(2))
        physical_layer_type: 'asynchronous' (BitField(2))
        frame_type: 'ack' (BitField(3))
    address: Address():
        master_address: 'primary_master' (Flag)
        burst_mode: 0 (Flag)
        address: 0x12eb021ce5 (SlaveAddress(38))
    expansion_bytes: Array():
    [
    ]
    command: 1 (Command)
    byte_count: 7 (UBInt8)
    payload: Command1_ReadPrimaryVariableResponse():
        response_code: 'success' (UBInt8)
        field_device_status: configuration_changed; more_status_available (FieldDeviceStatus)
        units: 139 (UBInt8)
        primary_variable: 0.0 (BFloat)
    check_byte: 6 (CheckByte)
```

List device commands

You can poll a list of device commands to see which are supported. This way it is possible to find undocumented commands.

If you do not specify a list of commands to be polled `0 .. 255` is used.

```
In [1]: find_device()
Using first device with address 0x52eb021ce5
Out[1]: 356130102501

In [2]: list_device_commands()
command 0 .. is supported
command 1 .. is supported
command 2 .. is supported
command 3 .. is supported
```

```
command 4 .. is supported
command 5 .. is supported
command 6 .. is not supported
command 7 .. is not supported
command 8 .. is not supported
command 9 .. is not supported
command 10 .. is supported
command 11 .. is not supported
command 12 .. is supported
command 13 .. is not supported
command 14 .. is supported
command 15 .. is not supported
[...]
command 248 .. is supported
command 249 .. is supported
command 250 .. is supported
command 251 .. is supported
command 252 .. is supported
command 253 .. is supported
command 254 .. is supported
command 255 .. is supported
Out[2]:
[0,
 1,
 2,
 3,
 4,
 5,
 10,
 12,
 14,
 [...]
 248,
 249,
 250,
 251,
 252,
 253,
 254,
 255]
```

You can specify the commands to poll by adding `commands=<iterable>`:

```
In [2]: list_device_commands(commands=[1, 2, 3])
command 1 .. is supported
command 2 .. is supported
command 3 .. is supported
Out[2]: [1, 2, 3]
```

Master address

To set the master address `htf.hart.HartShell.set_master_address` is used.

To set the master address to *secondary_master* enter:

```
In [1]: set_master_address('secondary_master')
```

Exit

To exit `hart-shell` enter `exit()`, `exit` or press `CTRL+d` followed by `y` and `Return`.

Method documentation

You can easily see the documentation for a method by adding a `?` at the end of the command.

```
In [1]: set_master_address?
Signature: set_master_address(master_address)
Docstring:
Set the current simulated master address.

Args:
    master_address (str): "primary_master" or "secondary_master"
```

Editing command payload interactively

By default a commands payload can be changed interactively. If the payload is empty there is nothing to be changed and the command is sent immediately.

For example the command 6 (set polling address) has a changeable payload. To change the polling address to `1` enter:

```
In [1]: find_device()
Using first device with address 0x1337000023
Out[1]: 82527125539

In [2]: cmd6()
Running Command 6
Enter value for HartFrame.payload.polling_address (UBInt8) [0]> 1
Enter value for HartFrame.payload.loop_current_mode (UBInt8) [0]>
Request:
HartFrame():
    delimiter: Delimiter():
        address_type: 'unique' (Flag)
        number_of_expansion_bytes: 0 (BitField(2))
        physical_layer_type: 'asynchronous' (BitField(2))
        frame_type: 'stx' (BitField(3))
    address: Address():
        master_address: 'primary_master' (Flag)
        burst_mode: 0 (Flag)
        address: 0 (BitField(38))
    expansion_bytes: Array():
    [
    ]
    command: 6 (UBInt8)
    byte_count: 0 (UBInt8)
    payload: Command6_WritePollingAddressRequest():
        polling_address: 1 (UBInt8)
```

```
        loop_current_mode: 0 (UBInt8)
    check_byte: 0 (CheckByte)
```

If you do not want to change a value simply press `Return`. The value in the `[ ]` is the current value that is not changed then.

Editing commands interactively

If you want to edit the whole request frame add a `edit_all=True` argument. In this case you can also change the command number, etc. on the fly.

```
In [1]: find_device()
Using first device with address 0x1337000023
Out[1]: 82527125539

In [2]: cmd1(edit_all=True)
Running Command 1
Enter value for HartFrame().delimiter.address_type (Enum of Flag) ['unique']>
Enter value for HartFrame().delimiter.number_of_expansion_bytes (BitField) [0]>

Request:
HartFrame():
    delimiter: Delimiter():
        address_type: 'unique' (Flag)
        number_of_expansion_bytes: 0 (BitField(2))
        physical_layer_type: 'asynchronous' (BitField(2))
        frame_type: 'stx' (BitField(3))
    address: Address():
        master_address: 'primary_master' (Flag)
        burst_mode: 0 (Flag)
        address: 0 (BitField(38))
    expansion_bytes: Array():
    [
    ]
    command: 1 (UBInt8)
    byte_count: 0 (UBInt8)
    payload: Command1_ReadPrimaryVariableRequest():
    check_byte: 0 (CheckByte)

Response:
HartFrame():
    delimiter: Delimiter():
        address_type: 'unique' (Flag)
        number_of_expansion_bytes: 0 (BitField(2))
        physical_layer_type: 'asynchronous' (BitField(2))
        frame_type: 'ack' (BitField(3))
    address: Address():
        master_address: 'primary_master' (Flag)
        burst_mode: 0 (Flag)
        address: 82527125539 (BitField(38))
```

```
    expansion_bytes: Array():
    [
    ]
    command: 1 (UBInt8)
    byte_count: 7 (UBInt8)
    payload: Command1_ReadPrimaryVariableResponse():
        response_code: 'buffer_overflow' (UBInt8)
        field_device_status: non-primary_variable_out_of_limits (FieldDeviceStatus)
        units: 123 (UBInt8)
        primary_variable: 456.78900146484375 (BFloat)
    check_byte: 193 (CheckByte)

Out[2]: <htf.hart.protocol.HartFrame at 0x7fead57fabe0>
```

Passing contents to a command

The contents for interactively editable payload or frame contents can also be passed using the `inputs=[..]` argument.

To set the polling address to `2` non-interactively enter:

```
In [1]: find_device()
Using first device with address 0x1337000023
Out[1]: 82527125539

In [2]: cmd6(inputs=[2, 0])
Running Command 6
Request:
HartFrame():
    delimiter: Delimiter():
        address_type: 'unique' (Flag)
        number_of_expansion_bytes: 0 (BitField(2))
        physical_layer_type: 'asynchronous' (BitField(2))
        frame_type: 'stx' (BitField(3))
    address: Address():
        master_address: 'primary_master' (Flag)
        burst_mode: 0 (Flag)
        address: 0 (BitField(38))
    expansion_bytes: Array():
    [
    ]
    command: 6 (UBInt8)
    byte_count: 0 (UBInt8)
    payload: Command6_WritePollingAddressRequest():
        polling_address: 2 (UBInt8)
        loop_current_mode: 0 (UBInt8)
    check_byte: 0 (CheckByte)
```

Enabling autocall

To enable the autocall-feature enter:

```
In [1]: %autocall 2
Automatic calling is: Full
```

Now you do not need to add brackets to the commands to be called:

```
In [1]: find_device
------> find_device()
Using first device with address 0x1337000023
Out[1]: 82527125539

In [2]: cmd1
------> cmd1()
Running Command 1
Request:
HartFrame():
    delimiter: Delimiter():
        address_type: 'unique' (Flag)
        number_of_expansion_bytes: 0 (BitField(2))
        physical_layer_type: 'asynchronous' (BitField(2))
        frame_type: 'stx' (BitField(3))
    address: Address():
        master_address: 'primary_master' (Flag)
        burst_mode: 0 (Flag)
        address: 0 (BitField(38))
    expansion_bytes: Array():
    [
    ]
    command: 1 (UBInt8)
    byte_count: 0 (UBInt8)
    payload: Command1_ReadPrimaryVariableRequest():
    check_byte: 0 (CheckByte)

Response:
HartFrame():
    delimiter: Delimiter():
        address_type: 'unique' (Flag)
        number_of_expansion_bytes: 0 (BitField(2))
        physical_layer_type: 'asynchronous' (BitField(2))
        frame_type: 'ack' (BitField(3))
    address: Address():
        master_address: 'primary_master' (Flag)
        burst_mode: 0 (Flag)
        address: 82527125539 (BitField(38))
    expansion_bytes: Array():
    [
    ]
    command: 1 (UBInt8)
    byte_count: 7 (UBInt8)
    payload: Command1_ReadPrimaryVariableResponse():
        response_code: 'buffer_overflow' (UBInt8)
        field_device_status: non-primary_variable_out_of_limits (FieldDeviceStatus)
        units: 123 (UBInt8)
        primary_variable: 456.78900146484375 (BFloat)
    check_byte: 193 (CheckByte)
```

```
Out[2]: <htf.hart.protocol.HartFrame at 0x7f39eef2c3c8>
```

Setting the protocol factory

To use the protocol factory created for your device enter:

```
hart-shell -c /dev/ttyUSB0 -d protocol_factory.get_hart_frame_by_device_type
```

`hart-shell` needs a protocol factory that created a HART-frame by device type.

In the example `protocol_factory` is an importable python file and `get_hart_frame_by_device_type` is a method within it.

Scripting the HART-Shell

You can script the HART-Shell by putting your commands into a text file for easy reuse.

```
$ cat >hart_commands.txt <<EOL
find_device()
cmd1()
EOL
$ hart-shell -c /dev/ttyUSB0 < hart_commands.txt
```

You can even use the autocall-feature.

HART-Monitor

The `HartMonitor` enables you to debug HART communications. It can be run within a python script or via command line.

The `HartMonitor` support two types of decoders. One is used in the underlying `HartApplicationLayer` to decode frames in the first decoding phase. This is called the `decoder_generator`.

To be able to monitor multiple different devices with different device specific commands it is possible to do a second step decoding with the `protocol_factory`.

This is a factory method that returns a device specific HART-frame by device address.

```
class htf.hart.monitor.HartMonitor(comport: str | None = None, decoder_generator:
Type[HartFrame] | Callable[[...], HartFrame] | None = None, protocol_factory: Callable[[...],
Type[HartFrame]] | None = None, interactive: bool = False, argv: List[str] | None = None)
```

A HART Monitor that can be used interactively.

Parameters:

- **comport** – the comport to be used where the HART modem is connected to.
- **decoder_generator=None** – a callable that returns a HartFrame instance with or without device specific commands that is used to decode all frames (if `protocol_factory` is `None`).
- **protocol_factory=None** – a protocol factory that returns a device specific HART frame parser with respect to the supplied device address. For every received frame the frame is decoded using the `decoder_generator` that may be `None` and after that a device specific decoder is created respecting the device address.
- **interactive=True** – if set to `True` the HART Monitor becomes interactive
- **argv=None** – used for testing, etc.

```
handle_exception(frame: HartFrame | None, exc: BaseException) → None
```

The exception handler that prints the formatted output. This method can be overwritten.

This overwritten method may or may not call `raise` at the end to raise the exception again.

Parameters:

- **frame** – the HART frame to be monitored.
- **exc** – the exception that can be formatted.

```
handle_frame(frame: HartFrame) → None
```

The frame handler that prints the formatted output. This method can be overwritten.

Parameters:
frame – the HART frame to be monitored.

```
run(frame_count: int = 0) → None
```

Run the monitor and display received HART frames.

Parameters:
frame_count – The number of frames to be received. `0` means forever.

```
set_decoder_generator(decoder_generator: Type[HartFrame] | Callable[[...], HartFrame] |
None = None) → None
```

Set the decoder generator. If `decoder_generator` is `None` `HartFrame` is used.

Parameters:
decoder_generator=HartFrame – a parser for HART frames.

```
set_protocol_factory(protocol_factory: Callable[[...], Type[HartFrame]] | None) → None
```

Set the protocol factory.

Parameters:
protocol_factory=None – a protocol factory that returns a device specific HART frame parser with respect to the supplied device address.

Command line usage

`htf` comes with a HART-Monitor command line utility called `hart-monitor`.

To start it enter

```
$ hart-monitor -c <comport>
```

Show help

```
$ hart-monitor -h
usage: hart-monitor [-h] -c COMPORT [-d Protocol database] [-V]

hart-monitor - HILSTER Testing Framework (HILSTER GmbH, http://hilster.io)

optional arguments:
  -h, --help            show this help message and exit
  -c COMPORT, --comport COMPORT
                        comport for HART communication
  -d Protocol database, --database Protocol database
                        An import string to the protocol database where device
                        specific HART frames can be found. See docs for
                        details.
  -V, --version         Show version and exit
```

Setting the protocol factory

To use the protocol factory created for your device enter:

```
hart-monitor -c /dev/ttyUSB0 -d protocol_factory.get_hart_frame_by_device_type
```

`hart-monitor` needs a protocol factory that created a HART-frame by device type.

In the example `protocol_factory` is an importable python file and `get_hart_frame_by_device_type` is a method within it.

Customizing the HART-Monitor

If a different output format is needed etc. the class `HartMonitor` can be subclassed and `handle_frame` can be overwritten.

In the following example every received frame is serializied to be printed on a single line with a timestamp.

```
from htf.hart.monitor import HartMonitor
import datetime

class MyHartMonitor(HartMonitor):
    def handle_frame(self, frame):
        frame_type = frame.delimiter.frame_type.get()
        direction = " ->"
        if frame_type == "ack":
            direction = "<- "
        command = frame.command.get()
        byte_count = frame.byte_count.get()
        address = frame.address.address.get()
        payload = str(frame.payload).replace("\n", "").replace("    ", ", ")
        print(str(datetime.datetime.utcnow()) +
              ": " + "%s %3i %s 0x%010x %3i (%s)" %
              (frame_type.upper(),
               command,
               direction,
               address,
               byte_count,
               payload))

if __name__ == "__main__":
    hm = MyHartMonitor(comport="COM46")
    hm.run(n=0)
```

HART Device Communication

The `HartDeviceCommunication` simplifies the communication with a HART device.

It can be either used as an instance or as a context block and helps to find a device and to query commands on that device.

```
class htf.hart.device_communication.HartDeviceCommunication(comport: str,
polling_addresses: List[int] = [0], device_address: int | None = None, decoder_generator:
Type[HartFrame] | Callable[[...], HartFrame] | None = None)
```

A communication to a HART device usable as a context block.

Parameters:

- **comport** – the comport to be used where the HART modem is connected to.
- **polling_addresses=[0]** – the polling addresses used to find a HART device.
- **device_address=None** – the initial HART device address. If set to an interger no device must be looked up.
- **decoder_generator=None** – a callable that returns a HartFrame instance with or without device specific commands.

```
close() → None
```

Close the HART application layer and close the HART interface supplied. Is called in __del__, too.

```
find_device(polling_addresses: List[int] | None = None) → int
```

Find the first HART device by polling all addresses stated in `polling_addresses` and use the first device found.

If no device is found an `AssertionError` is raised.

Parameters:
polling_addresses=[0] – the polling addresses used to find a HART device.
Returns:
Unique HART address of the first device found in polling.
Return type:
int

```
query(request: HartFrame, number_of_preambles: int = 5, preamble: bytes = b'\xff',
timeout: int | float = 1.0) → HartFrame | None
```

Query a HART command. The HART frame is encoded automatically.

Parameters:

- **request** – the hart frame to be sent.
- **number_of_preambles=5** – the number of preambles.
- **preamble='ÿ'** – `number_of_preambles` times `preamble` is sent before the frame content is sent.
- **timeout=1.0** – the timeout in seconds.

Returns:
if no frame was received `None` is returned.
Return type:
HartFrame or None

```
set_device_address(device_address: int) → None
```

Set the current HART device address.

Parameters:
device_address – the HART device address to be used (<= 38 bits)

In the following examples `Command 1` is queried on the first found device.

Usage with an instance:

```
from htf.hart import HartDeviceCommunication
from htf.hart.protocol import HartFrame
```

```
dc = HartDeviceCommunication(comport="/dev/ttyUSB1")
dc.find_device()

82527125539
cmd1_request = HartFrame(command=1)
cmd1_response = dc.query(cmd1_request)
print(cmd1_response)
    HartFrame():
        delimiter: Delimiter():
            address_type: 'unique' (Flag)
            number_of_expansion_bytes: 0 (BitField(2))
            physical_layer_type: 'asynchronous' (BitField(2))
            frame_type: 'ack' (BitField(3))
        address: Address():
            master_address: 'primary_master' (Flag)
            burst_mode: 0 (Flag)
            address: 82527125539 (BitField(38))
        expansion_bytes: Array():
        [
        ]
        command: 1 (UBInt8)
        byte_count: 7 (UBInt8)
        payload: Command1_ReadPrimaryVariableResponse():
            response_code: 'buffer_overflow' (UBInt8)
            field_device_status: non-primary_variable_out_of_limits (FieldDeviceStatus)
            units: 123 (UBInt8)
            primary_variable: 456.78900146484375 (BFloat)
        check_byte: 193 (CheckByte)

dc.close()
```

If a `device_address` is supplied `find_device` needs not to be called.

When used as a context block and no `device_address` is supplied `find_device` is called automatically. When the context block is left the underlying HART interface and Application Layer are closed automatically.

Example usage with a context block:

```
from htf.hart import HartDeviceCommunication
from htf.hart.protocol import HartFrame

with HartDeviceCommunication(comport="/dev/ttyUSB1") as dc:
    dc.find_device()
    cmd1_request = HartFrame(command=1)
    cmd1_response = dc.query(cmd1_request)
    print(cmd1_response)

82527125539
HartFrame():
    delimiter: Delimiter():
        address_type: 'unique' (Flag)
        number_of_expansion_bytes: 0 (BitField(2))
        physical_layer_type: 'asynchronous' (BitField(2))
        frame_type: 'ack' (BitField(3))
    address: Address():
```

```
        master_address: 'primary_master' (Flag)
        burst_mode: 0 (Flag)
        address: 82527125539 (BitField(38))
    expansion_bytes: Array():
    [
    ]
    command: 1 (UBInt8)
    byte_count: 7 (UBInt8)
    payload: Command1_ReadPrimaryVariableResponse():
        response_code: 'buffer_overflow' (UBInt8)
        field_device_status: non-primary_variable_out_of_limits (FieldDeviceStatus)
        units: 123 (UBInt8)
        primary_variable: 456.78900146484375 (BFloat)
    check_byte: 193 (CheckByte)
```

HART Fuzzing

The HART Testing Framework lets you easily run fuzzing tests on your HART device since it is based on OSER. You should have read the OSER documentation.

In the first example all HART frames shall have a valid checkbyte at the end. All commands from `0` to `255` shall be sent to the target. The payload is the default.

```
from htf.hart import HartFrame
import oser

h = HartFrame(0)

h.command.set_fuzzing_values(range(256))

for frame in h.fuzzing_iterator():
    encoded = frame.encode()  # update checkbyte
    print(frame)
    print(oser.to_hex(encoded))

HartFrame():
    delimiter: Delimiter():
        address_type: 'polling' (Flag)
        number_of_expansion_bytes: 0 (BitField(2))
        physical_layer_type: 'asynchronous' (BitField(2))
        frame_type: 'stx' (BitField(3))
    address: Address():
        master_address: 'primary_master' (Flag)
        burst_mode: 0 (Flag)
        address: 0 (BitField(6))
    expansion_bytes: Array():
    [
    ]
    command: 0 (UBInt8)
    byte_count: 0 (UBInt8)
    payload: Command0_ReadUniqueIdentifierRequest():
    check_byte: 130 (CheckByte)

   0|  1|  2|  3|  4
\x02\x80\x00\x00\x82
HartFrame():
```

```
    delimiter: Delimiter():
        address_type: 'polling' (Flag)
        number_of_expansion_bytes: 0 (BitField(2))
        physical_layer_type: 'asynchronous' (BitField(2))
        frame_type: 'stx' (BitField(3))
    address: Address():
        master_address: 'primary_master' (Flag)
        burst_mode: 0 (Flag)
        address: 0 (BitField(6))
    expansion_bytes: Array():
    [
    ]
    command: 1 (UBInt8)
    byte_count: 0 (UBInt8)
    payload: Command1_ReadPrimaryVariableRequest():
    check_byte: 131 (CheckByte)

# [%< %< %< %< %< %< %< %< %< %<]

   0|  1|  2|  3|  4|  5|  6|  7|  8|  9| 10| 11| 12| 13| 14| 15| 16| 17| 18| 19| 20| 21| 22| 23
\x02\x80\xfd\x13\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x6c
HartFrame():
    delimiter: Delimiter():
        address_type: 'polling' (Flag)
        number_of_expansion_bytes: 0 (BitField(2))
        physical_layer_type: 'asynchronous' (BitField(2))
        frame_type: 'stx' (BitField(3))
    address: Address():
        master_address: 'primary_master' (Flag)
        burst_mode: 0 (Flag)
        address: 0 (BitField(6))
    expansion_bytes: Array():
    [
    ]
    command: 254 (UBInt8)
    byte_count: 19 (UBInt8)
    payload: b''
    check_byte: 111 (CheckByte)

   0|  1|  2|  3|  4|  5|  6|  7|  8|  9| 10| 11| 12| 13| 14| 15| 16| 17| 18| 19| 20| 21| 22| 23
\x02\x80\xfe\x13\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x6f
HartFrame():
    delimiter: Delimiter():
        address_type: 'polling' (Flag)
        number_of_expansion_bytes: 0 (BitField(2))
        physical_layer_type: 'asynchronous' (BitField(2))
        frame_type: 'stx' (BitField(3))
    address: Address():
        master_address: 'primary_master' (Flag)
        burst_mode: 0 (Flag)
        address: 0 (BitField(6))
    expansion_bytes: Array():
    [
    ]
    command: 255 (UBInt8)
    byte_count: 19 (UBInt8)
    payload: b''
    check_byte: 110 (CheckByte)
```

```
   0|  1|  2|  3|  4|  5|  6|  7|  8|  9| 10| 11| 12| 13| 14| 15| 16| 17| 18| 19| 20| 21| 22| 23
\x02\x80\xff\x13\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x6e
```

In the second example the whole payload is random with a random length. All frames have a valid length field and a valid checkbyte.

```
from htf.hart import HartFrame

import oser
import string

h = HartFrame(0)

_random_length_iterator = oser.RandomIntegerFuzzingValue(a=0, b=40, count=1)

h.payload = oser.String(length=lambda self: next(_random_length_iterator()))
h.payload.set_fuzzing_values(
     oser.RandomBytesFuzzingValue(length=40, count=5)
)

for frame in h.fuzzing_iterator():
    encoded = frame.encode()  # update checkbyte
    print(frame)
    print(oser.to_hex(encoded))

HartFrame():
    delimiter: Delimiter():
        address_type: 'polling' (Flag)
        number_of_expansion_bytes: 0 (BitField(2))
        physical_layer_type: 'asynchronous' (BitField(2))
        frame_type: 'stx' (BitField(3))
    address: Address():
        master_address: 'primary_master' (Flag)
        burst_mode: 0 (Flag)
        address: 0 (BitField(6))
    expansion_bytes: Array():
    [
    ]
    command: 0 (UBInt8)
    byte_count: 28 (UBInt8)
    payload: b'\x8c\xdd\x0b]\x0cd\xf9\xde\x1a1fo\xea{@n\x82\x94dG

HART Slave Simulator

The `HartSlaveSimulator` allows simulation of HART slaves by sub-classing the `HartSlaveSimulator`.

```
class htf.hart.slave_simulator.HartSlaveSimulator(comport: str, decoder_generator:
Type[HartFrame] | Callable[[...], HartFrame] | None = None, polling_address: int = 0,
device_type: int = 0, device_id: int = 0)
```

```
close() → None
```

Closes the HART Application Layer of the simulator.

```
handle_command0(frame: HartFrame) → HartFrame | None
```

Handler for command 0 HART requests. Checks if the polling address in the frame matches the one set in the simulator.

Parameters:
frame – the command 0 HART request
Returns:
the response containing device type, device id and protocol revision
Return type:
HartFrame

```
handle_default(frame: HartFrame) → None
```

Default handler for HART requests that don't have a specialized handler.

Parameters:

frame – the HART frame to handle

```
handle_exception(exc: BaseException) → None
```

The exception handler that prints the raised exception.

Parameters:
exc – the exception that was raised.

```
handle_frame(frame: HartFrame) → None
```

Checks that the device address matches and whether responses to the HART command are disabled. Calls possible frame callbacks and sends a HART response frame if there is one.

Parameters:
frame – the HART frame to handle

```
register_frame_callback(callback: Callable[[float, HartFrame], None]) → None
```

Registers a callback for every HART request and response that is received or send out. Callbacks are called with two arguments: a timestamp and the HART frame.

Parameters:
callback – callback for HART frames

```
run(frame_count: int = 0) → None
```

Run the HART device simulator

Parameters:
frame_count – The number of frames to handle. `0` means forever.

```
run_while(condition: bool | Callable[[...], bool]) → None
```

Simulate while the condition is `True`.

Parameters:
condition – the condition for the run.

```
set_response_enabled(command: int | str, enabled: bool = True) → None
```

Enables/disables responses to a given HART command number. Responses to all commands are enabled by default.

Parameters:

- **command** – HART command number or “any”
- **enabled=True** – enabled state

```
unregister_frame_callback(callback: Callable[[float, HartFrame], None]) → None
```

Unregisters a previously registered callback.

Parameters:
callback – callback for HART frames

If you’d like to add other handlers for different commands simply add a handler method that fits the name convention `handle_command<cmd>` where `<cmd>` is the desired command number.

```
from htf.hart.slave_simulator import HartSlaveSimulator
from htf.hart import HartFrame, ResponseCode, FieldDeviceStatus
import oser

# Command abstractions
class Command123_ReadValueRequest(oser.ByteStruct):
    def __init__(self):
        super(Command123_ReadValue, self).__init__()
        self.double_value = oser.Flag(False)

class Command123_ReadValueResponse(oser.ByteStruct):
    def __init__(self):
        super(Command123_ReadValue, self).__init__()
        self.response_code = ResponseCode()
        self.field_device_status = FieldDeviceStatus()
        self.value = oser.UBInt8()

# Decoder generator extending the default HART frame implementation
class MyHartDeviceFrame(HartFrame):

    def requests_generator(self):
        for command, parser in super(MyHartDeviceFrame, self).requests_generator():
            yield command, parser
        yield 123, oser.Lazy(Command123_ReadValueRequest)

    def responses_generator(self):
        for command, parser in super(MyHartDeviceFrame, self).responses_generator():
            yield command, parser
        yield 123, oser.Lazy(Command123_ReadValueResponse)

# Slave simulator with the extended HART frame (MyHartDeviceFrame)
class MyHartDevice(HartSlaveSimulator):

    # Initialization of the device attributes
    def __init__(self, comport):
            super(MyHartDevice, self).__init__(comport, decoder_generator=MyHartDeviceFrame,
                                               polling_address=0, device_type=0x1337,
                                               device_id=0x23)
        self.value = 321

    # Implementation of the response behavior
```

```
    def handle_command123(self, request):
        response = self._create_response(request)

        if request.payload.double_value.get():
            response.payload.value.set(self.value * 2)
        else:
            response.payload.value.set(self.value)

        return response

if __name__ == "__main__":
    sim = MyHartDevice("COM1")
    sim.run(10)
```

Changelog

htf-hart-3.2.0

- ship `cp312-abi3` wheels that are compatible with Python 3.12 and newer versions

htf-hart-3.1.6

- implement Cyber Resilience Act Conformity (CRA)
- update dependencies

htf-hart-3.1.5

- add support for Python 3.13

htf-hart-3.1.4

- add requirements for validation purposes

htf-hart-3.1.3

- add build environment data for validation purposes

htf-hart-3.1.2

- `htf-hart` can now be used standalone

htf-hart-3.1.1

- add support for Python 3.12

htf-hart-3.1.0

- add type-hints
- use `hlm-3.1`
- use `oser-3.1`

htf-hart-3.0.1

- add support for Python 3.11

htf-hart-3.0.0

- extract `htf-hart` from `htf`

Communication

This chapter describes the modules for the asynchronous communication framework.

Pluggable Notifier

The `htf.communication.PluggableNotifier` is an observer that lets subjects register tuples of `name`, `filterExpression` and a `callback`.

When data is input all registered subjects are used the following way. First the `filterExpression` is called with the data as a parameter. If `True` is returned the callback is called with the data as a parameter.

With the `htf.communication.PluggableNotifier` you can create an asynchronous communication framework easily.

```
class htf.communication.PluggableNotifier(verbosity: int = 0,
raise_exceptions: bool = False, filter_exception_handler: Callback | None = None,
callback_exception_handler: Callback | None = None)
```

`PluggableNotifier` implements an observer pattern. Subjects can register tuples consisting of executable filter expressions and callbacks to be notified about events.

There is a method to enqueue new items and a thread to apply filters on items. Communication between method and thread is done via a queue.

`PluggableNotifier` extends `threading.Thread`.

Parameters:

- **verbosity** – if set to 1 debug messages are printed to stdout
- **raise_exceptions** – if set to `True` exceptions are raised if a filter expression or a callback raises an exception. This may be used for debugging. In case of an exception `stop` is called so no further items can be put in.
- **filter_exception_handler** – a callback that is called to handle a raised exception in a filter expression. If the `filter_exception_handler` returns `True` the exception is not raised afterwards. Else the exception handler raises the catched exception and stopps the thread. The supplied handler musst accept `name` and `item` arguments. `name` is the callback name supplied by `register` and `item` is the supplied item from `input`.

- **callback_exception_handler** – a callback that is called to handle a raised exception in a callback. If the `callback_exception_handler` returns `True` the exception is not raised afterwards. Else the exception handler raises the catched exception and stopps the thread. The supplied handler musst accept `name` and `item` arguments. `name` is the callback name supplied by `register` and `item` is the supplied item from `input`.

```
get_filter_names() → List[str]
```

Get the filter names.

Returns:
a sorted list containing the filter names.
Return type:
list of str

```
input(item: Any) → None
```

Input an `item` to be used with all registered subjects.

Parameters:
item – an item to be processed.
Raises:

- **RuntimeError** – if `stop`
- **was called before** –

```
join(timeout: float | None = 1.0) → None
```

Wait until the thread ends.

Parameters:
timeout – the timeout in seconds. Default: 1.0 seconds.

```
register(name: str, filter_expression: Callback, callback: Callback) → None
```

Register a tuple of *name*, *filter_expression* and a *callback*.

Parameters:

- **name** – a name for the tuple (for debugging, see `verbosity`).
- **filter_expression** – a callable filter expression (see `htf.filters` for more information) or a method that is called. `filter_expression` is called with the `item` from `input` as a parameter. If `filter_expression` returns *True* the callback is called with the same *item*.
- **callback** – a callable object that is called in case `filter_expression(item)` returns `True`.

```
run() → None
```

Method representing the thread's activity.

You may override this method in a subclass. The standard run() method invokes the callable object passed to the object's constructor as the target argument, if any, with sequential and keyword arguments taken from the args and kwargs arguments, respectively.

```
stop() → None
```

Stop the thread.

```
unregister(name: str) → None
```

Unregister a callback with a given `name`.

Parameters:
name – the name of the callback to be unregistered.
Raises:
KeyError – if `name` was not found in `notifications`.

Notification Callbacks

Notification callbacks can be used in `htf.communication.PluggableNotifier` as the *callback*.

For example you can enqueue an item into a queue the callee just created to asynchronously receive data.

Example:

```
from htf.communication import PluggableNotifier, enqueueItem
import queue # or Queue in Python 2

pn = PluggableNotifier()
q = queue.Queue()
pn.register("subject", filterExpression=lambda *args,
            **kwargs: kwargs["item"]=="example item", callback=enqueueItem(q))
pn.input("example item") # is passed
item = q.get(block=True, timeout=1)
print(item) # "example item"
pn.input("another item") # is filtered out
item = q.get(block=True, timeout=1) # raises Queue.Empty
```

```
htf.communication.notification_callbacks.enqueue_item(queue: Queue) → Callable[[str, Any],
None]
```

Enqueues `item` into `queue`. This way asynchronous communication can be set up easily.

Parameters:
queue (*queue.Queue*) – a queue to be used.

Returns:
an anonymous method that can be called with an `item` that is put into `queue`.
Return type:
callable

SSH Client

With the SSH Client you can run commands remotely via SSH.

```
class htf.communication.SSHClient
```

`SSHClient` executes commands remotely using ssh.

```
close() → None
```

Close current ssh connection.

```
connect(hostname: str, username: str | None = None, password: str | None = None) → None
```

Establish an ssh connection.

Parameters:

- **hostname** – the hostname or ip address
- **username=None** – The username to be used. If set to `None` the current username is used instead of using the ssh keys in your system.
- **password=None** – The password for `username`. If set to `None` the password for `username` or the current username is used.

```
execute(*command: str) → Tuple[int, bytes, bytes]
```

Execute a command remotely via ssh.

Parameters:
***command** – the command to be executed.
Returns:
a tuple containing exitcode, stdout and stderr of the executed command.
Return type:
tuple

SFTP Client

With the SFTP Client it is possible to do file operations remotely via SSH.

```
class htf.communication.SFTPClient
```

`SFTPClient` lets you access files via sftp protocol.

```
close() → None
```

Close current sftp connection.

```
connect(hostname: str, username: str | None = None, password: str | None = None) → None
```

Establish an sftp connection.

Parameters:

- **hostname** – the hostname or ip address
- **username=None** – The username to be used. If set to `None` the current username is used instead of using the ssh keys in your system.
- **password=None** – The password for `username`. If set to `None` the password for `username` or the current username is used.

```
get(remotepath: str, localpath: str) → None
```

Copies file identified by `remotepath` to `localpath` using sftp protocol.

Parameters:

- **remotepath** – the remote file to be copied
- **localpath** – the local path where the field is copied to

```
put(localpath: str, remotepath: str) → SFTPAttributes
```

Copies file identified by `localpath` to `remotepath` using sftp protocol.

Parameters:

- **localpath** – the local path to be copied
- **remotepath** – the remote file where the field is copied to

Returns:
the result of os.stat
Return type:
SFTPAttributes

```
remove(remotepath: str) → None
```

Removes a file identified by `remotepath`.

Parameters:
remotepath – the path for the file to be removed
Raises:
IOError – if the path is not a file

```
rename(oldpath: str, newpath: str) → None
```

Remotely renames a file or a folder.

Parameters:

- **oldpath** – the file or folder to be renamed
- **newpath** – the new file- or foldername

Raises:
IOError – if something goes wrong

```
unlink(remotepath: str) → None
```

Removes a file identified by `remotepath`.

Parameters:
remotepath – the path for the file to be removed
Raises:
IOError – if the path is not a file

SLIP — Serial Line Internet Protocol

SLIP contains a mixin to be used to implement SLIP-based communications.

If you don't know about SLIP you should first read RFC 1055.

The `htf.communication.SlipMixin` contains two methods for encoding and decoding SLIP-encoded communication frames.

```
class htf.communication.SlipMixin
```

The `SlipMixin` helps to encode and decode frames transferred in the Serial Line Internet Protocol.

It cannot be used standalone and must be mixed into a class that implements the `htf.communication.SlipInterface`.

```
slip_receive_frame(timeouts: int | None = None, max_length: int = 1024) → bytes | None
```

Receive a frame encoded in the Serial Line Internet Protocol and return the decoded frame.

Parameters:

- **timeouts=None** – the number of timeouts until None is returned. The timeout depends on the mixing class and underlying communication system.
- **max_length=1024** – maximum number of bytes that will be received, not including ESC. Prevents the method from perpetually blocking.

Returns:
the decoded frame if a frame was received or
`None` if no frame was received.

Return type:
bytes or None

```
slip_send_frame(frame: bytes) → None
```

Send a frame encoded in the Serial Line Internet Protocol.

Parameters:
frame – the frame to be sent.

A class can subclass `htf.communication.SlipMixin` and must implement the `htf.communication.SlipInterface`.

```
class htf.communication.SlipInterface
```

```
receive_byte() → bytes
```

Receive a single byte. If no byte was received, `None` is returned to tell about a timeout.

Returns:
a single byte that was received or `None` **if a**
timeout occurred.

Return type:
bytes or None

```
send_byte(byte: bytes) → None
```

Send a single byte.

Parameters:
byte – a single byte to be sent.

In the following example one-way SLIP communication is established with a client and a server.

SLIP-Client:

```
from htf.communication import SlipMixin
import serial

class SlipClient(SlipMixin):
    def __init__(self, comport):
        self._serial = serial.Serial(comport, 115200,
                                     timeout=1.0, rtscts=False)

    def send_byte(self, byte):
        self._serial.write(byte)

    def receive_byte(self):
        return self._serial.read(1)

    def send(self, message):
        if not isinstance(message, bytes):
            message = message.encode()
        self.slip_send_frame(message)

if __name__ == "__main__":
    s = SlipClient("/dev/ttyUSB1")
    message = "Hello World!"
    s.send(message)
```

SLIP-Server:

```
from htf.communication import SlipMixin
import serial

class SlipServer(SlipMixin):
    def __init__(self, comport):
        self._serial = serial.Serial(comport, 115200,
                                     timeout=1.0, rtscts=False)

    def send_byte(self, byte):
        self._serial.write(byte)

    def receive_byte(self):
        return self._serial.read(1)

    def send(self, message):
        if not isinstance(message, bytes):
            message = message.encode()
        self.slip_send_frame(message)

    def receive(self):
        message = self.slip_receive_frame(timeouts=3)
        print("Received message:", message)

if __name__ == "__main__":
    s = SlipServer("/dev/ttyUSB2")
    while True:
        s.receive()
```

Changelog

htf-communication-4.1.0

- ship `cp312-abi3` wheels that are compatible with Python 3.12 and newer versions

- remove all camel-case methods
- add type-hints
- use `hlm-3.1`
- use `oser-3.1`

htf-communication-3.0.1

- add support for Python 3.11

htf-communication-3.0.0

- extract `htf-communication` from `htf`

I/O — Input and Output

Xentara — Real-Time Automation Platform

Introduction

Xentara is a modular, secure and powerful Real-Time Automation Platform. You can find more information at the Xentara website.

`htf` includes a websocket-client to interact with the Xentara runtime. Thus, users can for example deploy tests on their machines and execute tests remotely.

The Xentara-client is async-only.

Open a Connection

To open a connection, instantiate `XentaraClient` and await it.

```
client = await XentaraClient(
    url="wss://xentara-host/api/ws",
    root_element="Hardware",
)
```

> **Note**
>
> Don't forget the `await` statement!

Alternatively use `create`.

```
client = await XentaraClient.create(
    url="wss://xentara-host/api/ws",
    root_element="Hardware",
)
```

The root element (`root_element`) must match the configuration Xentara was started with. The contents are browsed and fetched automatically on instantiation.

Authentication

The Xentara-client supports basic authentication.

The credentials are simply added to the url, i.e.:

```
client = await XentaraClient(
    url="wss://<user>:<password>@xentara-host/api/ws",
)
```

where `<username>` is the username and `<password>` is the password to be used.

TLS/SSL

Use `wss://` in the url for a TLS/SSL secured connection and `ws://` for an unsafe and unencrypted connection.

Self-signed certificates

To disable the TLS/SSL certificate verification, just add `verify_ssl=False`.

```
client = await XentaraClient(
    url="wss://<user>:<password>@xentara-host/api/ws",
    root_element="Hardware",
    verify_ssl=False,
)
```

Close a Connection

To close an open connection, simply run:

```
await client.close()
```

Reading values

To read a value, call `read`:

```
value = await client.read("<element>")
```

`<element>` is a descriptor of a Xentara element, for example `"Hardware.EtherCAT Bus.EL2624.Output 1"`.

In addition, the Xentara-client can be used like a dictionary to read values.

```
value = await client["<element>"].read()
```

Writing values

To write a value, call `write`:

```
await client.write("<element>", value)
```

`<element>` is a descriptor of a Xentara element, for example `"Hardware.EtherCAT Bus.EL2624.Output 1"`.

The Xentara-client can be used like a dictionary to write values.

```
await client["<element>"].write(value)
```

Subscriptions

To subscribe to changes, use the `subscribe` function that returns a `Subscription`.

The `htf.xentara.Subscription` returns an async iterable that can be used in different ways. Each iteration yields an `Event`.

The easiest way to use a subscription is:

```
async with client.subscribe("<element>") as subscription:
    for i in range(5):
        event = await subscription.receive()
        value = event.value
        print(f"{i}: {event=}")
```

`aiter` can also be used explicitly:

```
async with client.subscribe("<element>") as subscription:
    iterator = aiter(subscription)
    for i in range(5):
        event = await iterator.__anext__()
        value = event.value
        print(f"{i}: {event=}")
```

For an infinite number of received values, `async for` can be used.

```
subscription = client.subscribe("<element>")

async with subscription as subscription:
    async for event in subscription:
        value = event.value
        print(f"{i}: {event=}")
```

String Representation

The Xentara client can be printed to get information about it.

```
print(client)
```

Use the Client like a Dictionary

To get the available elements, the `XentaraClient` can be used like a dictionary.

```
keys = client.keys()
values = client.values()
items = client.items()
length = len(client)
```

XentaraClient

```
class htf.xentara.XentaraClient(url: str, root_element: str = 'Hardware', verify_ssl: bool =
True)
```

The Xentara websocket client.

Parameters:

- **url** – The url to connect to the Xentara server.
- **root_element** – The root element to browse for elements. This is set in the Xentara configuration.
- **verify_ssl** – if set to `False` TLS/SSL certificate verification is switched off. Default is `True`.

```
async close() → None
```

Close the connection.

```
async copy() → XentaraClient
```

Return a copy of the instance with a new websocket connection.

```
async classmethod create(url: str, root_element: str = 'Hardware', verify_ssl: bool =
True) → XentaraClient
```

Create the Xentara client. Is called when the class instance is awaited, too.

Parameters:

- **url** – The url to connect to the Xentara server.
- **root_element** – The root element to browse for elements. This is set in the Xentara configuration.
- **verify_ssl** – if set to `False` TLS/SSL certificate verification is switched off. Default is `True`.

```
async read(element: str) → Any
```

Read the current value.

Returns:
the current value
Return type:
Any

```
subscribe(element: str, maximum_update_interval: int = 500, minimum_update_interval: int
= 1000) → Subscription
```

Create a subscription.

Parameters:

- **element** – The element to be subscribed.
- **maximum_update_interval** – the maximum update interval in milliseconds (default: 500)
- **minimum_update_interval** – the minimum update interval in milliseconds (default: 1000)

Returns:
the instance of the subscription
Return type:
Subscription

```
async write(element: str, value: Any) → Any
```

Write a value.

Parameters:
value – the value to be written

Element

```
class htf.xentara.Element(client: XentaraClient, name: str)
```

An element to read and write values. Used when :class:~`htf.xentara.XentaraClient` is used like a dictionary.

```
async read() → Any
```

Read the current value.

Returns:
the current value
Return type:
Any

```
async write(value: Any) → Any
```

Write a value.

Parameters:
value – the value to be written

Subscription

```
class htf.xentara.Subscription(client: XentaraClient, element: str, maximum_update_interval:
int = 500, minimum_update_interval: int = 1000)
```

Subscriptions for Xentara elements.

Users will never call this method directly.

Parameters:

- **client** – the current Xentara client's instance (passed automatically)
- **element** – the name of the element the subscription is for
- **maximum_update_interval** – the maximum update interval in milliseconds (default: 500)
- **minimum_update_interval** – the minimum update interval in milliseconds (default: 1000)

```
async receive() → Event
```

Receive the next event in the subscription.

```
async start() → None
```

Start the subscription.

```
async stop() → None
```

Stop the subscription.

Event

```
class htf.xentara.Event(timestamp: float, name: str, uuid: UUID, value: Any)
```

Yielded in `Subscription` when used as an async iterator.

```
name: str
```

the name of the element

```
timestamp: float
```

the timestamp as a float

```
uuid: UUID
```

the uuid of the element

```
value: Any
```

the current value of the element

LabJack — DAQ devices

Introduction

htf offers native support for LabJack's DAQ devices to easily use them in tests without the need of a driver (except on Windows, where a driver is necessary).

Limitations

Streaming is not yet implemented.

Preparation on Linux

Simply install `libusb` and everything works out of the box, even from within Docker.

Driver installation on Windows

The easiest way to use LabJack devices via USB is to install the LJM software package that includes an USB driver. It can be downloaded here.

Alternatively you can use libusb as a driver for USB communication. To do that, please follow the installation instructions from `libusb`.

Supported devices

htf supports the following LabJack devices

- T4
- T7
- T7-Pro
- T8

List USB devices

To list connected USB devices, run

```
labjack list
# 0cd5:0007 (bus 1, device 76): LabJack T7 'My_T7_123' Ethernet: 192.168.0.100 Wifi: <not connected>
```

The output lists all connected devices with the device name and IP addresses. It does not search for devices via network.

Opening USB devices

To open any USB device, do not pass any parameters when instantiating a client.

```
from htf.labjack import T7
labjack_device = T7()
print(labjack_device)
# <T7 connection='Modbus TCP' name='My_T7_1896' host=192.168.0.100 port=502>
```

To open a USB device explitly pass the device name.

```
from htf.labjack import T7
labjack_device = T7(name="My_T7_1234")  # use your device's name instead
print(labjack_device)
# <T7 connection='USB' name='My_T7_1234'>
```

Opening Modbus TCP devices

To open a device via Modbus TCP use the ip address or host name when instantiating the client.

```
from htf.labjack import T7
```

```
labjack_device = T7(host="my-labjack-device")
print(labjack_device)
# <T7 connection='Modbus TCP' name='My_T7_1234' host='my-labjack-device' port=502>
# or
labjack_device = T7(host="192.168.0.100")
print(labjack_device)
# <T7 connection='Modbus TCP' name='My_T7_1234' host='192.168.0.100' port=502>
```

Interaction with the devices

All devices have a respective class named after the device name, which provides attributes that can be read or written to to access Modbus registers. In addition, convenience functions are provided to improve ease of use.

The attributes have the same name as the Modbus registers, but in lower case.

For example the following code reads the current value from `AIN0` as `float`. The corresponding Modbus register is read automatically.

```
from htf.labjack import T7

labjack_device = T7(host="my-labjack-device")
current_ain: float = labjack_device.ain0
```

To output `3 V` on `DAC0`, simply run:

```
from htf.labjack import T7

labjack_device = T7(host="my-labjack-device")
labjack_device.dac0 = 3.0
```

Transactions

By default all communication with a LabJack devices is locked (thread-safe). Additionally, all convenience functions use another lock to assure that multiple commands are run without an interruption.

To run multiple commands from user code, use a with statement:

```
from htf.labjack import T7

labjack_device = T7(host="my-labjack-device")
with labjack_device as device:
    # all commands in this context block are executed as a transaction that cannot be interrupted
    current_ain0: float = device.ain0
    current_ain1: float = device.ain1
    current_ain2: float = device.ain2
```

Examples

Digital Input

To read the current state of `EIO0`, run:

```
from htf.labjack import T7

device = T7(host="my-labjack-device")
eio0: int = device.eio0
print(f"{eio0=}")
```

Digital Output

To set the current state of `EIO0` to 1, run:

```
from htf.labjack import T7

device = T7(host="my-labjack-device")
device.eio0 = 1
```

Analog Input

To read the current value of `AIN0`, run:

```
from htf.labjack import T7

device = T7(host="my-labjack-device")
device.setup_ain0(range_=5.0, settling_time_us=0, resolution_index=0)  # optional
ain0: float = device.ain0
print(f"{ain0=}")
```

Analog Output

To set `DAC0` to `5 V`, run:

```
from htf.labjack import T7

device = T7(host="my-labjack-device")
device.dac0 = 5.0
```

Example usage in tests

The following example shows a self test for LabJack T7 in a test with a fixture and settings.

Local settings are located in `settings.yml`:

```
labjack:
  hostname: 10.0.0.83
```

A fixture to use the device is located in `fixtures.py`:

```
import htf
from htf.labjack.t7 import T7

@htf.fixture(scope="test")
def t7(settings: htf.Settings) -> T7:
    device = T7(host=settings.labjack.hostname)
    yield device
    device.close()
```

An example test can be found in `example.py`:

```
import htf

def test_t7_analog_io(t7, step) -> None:
    """
    External wiring:
    DAC0<--->AIN0+AIN1
    DAC1<--->AIN2+AIN3
    """
    with step("Test analog IO"):
        with step("Setup AIN"):
            t7.setup_ain_all(range_=5.0, settling_time_us=10000)
            t7.setup_ain0(range_=5.0, settling_time_us=10000)
            t7.setup_ain1(range_=5.0, settling_time_us=10000)
            t7.setup_ain2(range_=5.0, settling_time_us=10000)
            t7.setup_ain3(range_=5.0, settling_time_us=10000)

        with step("Set all DAC to 0 V"):
            t7.dac0 = 0.0
            t7.dac1 = 0.0
            htf.assert_almost_equal(t7.ain0, 0.0, places=1)
            htf.assert_almost_equal(t7.ain1, 0.0, places=1)
            htf.assert_almost_equal(t7.ain2, 0.0, places=1)
            htf.assert_almost_equal(t7.ain3, 0.0, places=1)

        with step("Set DAC0 to 5 V"):
            t7.dac0 = 5.0
            htf.assert_almost_equal(t7.ain0, 5.0, places=1)
            htf.assert_almost_equal(t7.ain1, 5.0, places=1)
            htf.assert_almost_equal(t7.ain2, 0.0, places=1)
            htf.assert_almost_equal(t7.ain3, 0.0, places=1)

        with step("Set DAC1 to 3 V"):
            t7.dac1 = 3.0
            htf.assert_almost_equal(t7.ain0, 5.0, places=1)
            htf.assert_almost_equal(t7.ain1, 5.0, places=1)
            htf.assert_almost_equal(t7.ain2, 3.0, places=1)
```

```
            htf.assert_almost_equal(t7.ain3, 3.0, places=1)

def test_t7_digital_io(t7, step) -> None:
    """
    External wiring:

    FIO0<--->FIO1
    FIO2<--->GND
    FIO3<--->NC
    """
    with step("Test digital IO"):
        with step("Set FIO0 and FIO1 to input"):

            t7.fio1  # read value to make FIO1 an input

        with step("Check that FIO0 and FIO1 both inputs"):
            print(f"{t7.fio0=}")
            print(f"{t7.fio1=}")
            htf.assert_equal(t7.fio0, 1)
            htf.assert_equal(t7.fio1, 1)

        with step("Check that FIO0 drives HIGH and FIO1 reads HIGH"):
            t7.fio0 = 1
            htf.assert_equal(t7.fio0, 1)
            htf.assert_equal(t7.fio1, 1)

        with step("Set FIO0 and FIO1 to input"):
            t7.fio0  # read value to make FIO0 an input
            t7.fio1  # read value to make FIO1 an input

        with step("Check that FIO1 drives HIGH and FIO0 reads HIGH"):
            t7.fio1 = 1
            htf.assert_equal(t7.fio1, 1)
            htf.assert_equal(t7.fio0, 1)

        with step("Set FIO0 and FIO1 to input"):
            t7.fio0  # read value to make FIO0 an input
            t7.fio1  # read value to make FIO1 an input

        with step("Check that FIO2 reads GND"):
            htf.assert_equal(t7.fio2, 0)

        with step("Check that FIO3 reads HIGH"):
            htf.assert_equal(t7.fio3, 1)

if __name__ == "__main__":
    htf.main()
```

LabJack T4

```
class htf.labjack.T4(*, name: str | None = None, host: str | None = None, port: int = 502,
debuglevel: int = 0, timeout: float = 1.0, retries: int = 0)
```

LabJack adapter for the T4.

Parameters:

- **name** – If name is set the USB device's name is checked against it. If host is None a USB device is opened.
- **host** – If host is set a Modbus-TCP connection is opened. Name must not be set at the same time.
- **port** – The Modbus-TCP port to be used
- **debuglevel** – If set the Modbus packets are printed
- **timeout** – The timeout for every request
- **retries** – The number of retries for Modbus communication

```
property ain0: float
```

Returns the voltage of the specified analog input.

Register: AIN0 (AIN#(0:11)@0)

Address: 0

```
property ain0_binary: int
```

Returns the 24-bit binary representation of the specified analog input. If you prefer 16-bit representation, simply divide this by 256. This is for command-response only. Stream always returns binary and LJM applies cal constants, so the LJM config flag LJM_STREAM_AIN_BINARY is used to get binary values.

Register: AIN0_BINARY (AIN#(0:254)_BINARY@0)

Address: 50000

```
property ain0_ef_config_a: int
```

Function dependent on selected feature index.

Register: AIN0_EF_CONFIG_A (AIN#(0:149)_EF_CONFIG_A@0)

Address: 9300

```
property ain0_ef_config_b: int
```

Function dependent on selected feature index.

Register: AIN0_EF_CONFIG_B (AIN#(0:149)_EF_CONFIG_B@0)

Address: 9600

```
property ain0_ef_config_c: int

property ain0_ef_read_d: float
```

Function dependent on selected feature index.

Register: AIN0_EF_READ_D (AIN#(0:149)_EF_READ_D@0)

Address: 7900

```
property ain0_negative_ch: int
```

Specifies the negative channel to be used for each positive channel. 199=Default=> Single-Ended.

Register: AIN0_NEGATIVE_CH (AIN#(0:3)_NEGATIVE_CH@0)

Address: 41000

```
property ain0_range: float
```

The range/span of each analog input. Write the highest expected input voltage.

Register: AIN0_RANGE (AIN#(0:3)_RANGE@0)

Address: 40000

```
property ain0_resolution_index: int
```

The resolution index for command-response and AIN-EF readings. A larger resolution index generally results in lower noise and longer sample times.

Register: AIN0_RESOLUTION_INDEX (AIN#(0:3)_RESOLUTION_INDEX@0)

Address: 41500

```
property ain0_settling_us: float
```

Settling time for command-response and AIN-EF readings.

Register: AIN0_SETTLING_US (AIN#(0:3)_SETTLING_US@0)

Address: 42000

```
property ain1: float
```

Returns the voltage of the specified analog input.

Register: AIN1 (AIN#(0:11)@1)

Address: 2

```
property ain10: float
```

Returns the voltage of the specified analog input.

Register: AIN10 (AIN#(0:11)@10)

Address: 20

```
property ain100_binary: int
```

Returns the 24-bit binary representation of the specified analog input. If you prefer 16-bit representation, simply divide this by 256. This is for command-response only. Stream always returns binary and LJM applies cal constants, so the LJM config flag LJM_STREAM_AIN_BINARY is used to get binary values.

Register: AIN100_BINARY (AIN#(0:254)_BINARY@100)
